

Jerry Gilfoyle's Enotebook

DOE 2000 Electronic Notebook

Table of Contents

1. test (Jerry Gilfoyle)	[Last Modified Wed Nov 4 16:14:02 2009 (GMT)]
2. sector 6 2gen fits (gpg)	[Last Modified Thu Jun 2 11:17:28 2011 (GMT)]
3. sector 5 results (gpg)	[Last Modified Mon Jul 19 20:35:05 2004 (GMT)]
4. sector 4 results (gpg)	[Last Modified Tue Jul 20 16:08:57 2004 (GMT)]
5. sector 1 results (gpg)	[Last Modified Tue Jul 20 18:13:35 2004 (GMT)]
6. sector 3 results (gpg)	[Last Modified Tue Jul 20 21:21:50 2004 (GMT)]
7. sector 2 results (gpg)	[Last Modified Thu Jul 29 17:26:01 2004 (GMT)]
8. momentum corrections 1 (gpg)	[Last Modified Tue Aug 3 13:30:35 2004 (GMT)]
9. checking CC (gpg)	[Last Modified Mon Aug 2 20:30:10 2004 (GMT)]
10. 3gen fits for sectors 1-6 (gpg)	[Last Modified Tue Aug 24 22:33:05 2004 (GMT)]
11. testing fiducial function (gpg)	[Last Modified Mon Aug 30 18:11:09 2004 (GMT)]
12. SJ calculations at 12 GeV (GPG)	[Last Modified Sat Jul 23 16:57:06 2011 (GMT)]
13. Momentum corrections (gpg)	[Last Modified Sun Sep 12 23:06:19 2004 (GMT)]
14. Momentum corrections 2 (gpg)	[Last Modified Wed Sep 29 20:32:39 2004 (GMT)]
15. Momentum corrections 3 (gpg)	[Last Modified Wed Feb 16 01:59:41 2005 (GMT)]
16. recent ALTp results (gpg)	[Last Modified Wed Nov 24 17:09:10 2004 (GMT)]
17. ALTp with and without electron fiducial cuts at 2.6n (gpg)	[Last Modified Wed Jan 11 01:23:11 2006 (GMT)]
18. ALTp comparison with different Quasielastic cuts (gpg)	[Last Modified Wed Dec 1 16:20:34 2004 (GMT)]
19. selecting OE events (gpg)	[Last Modified Thu Dec 9 13:28:43 2004 (GMT)]
20. More tests of efid and pcorr (gpg)	[Last Modified Wed Dec 15 16:28:20 2004 (GMT)]
21. high ALTp point for $1.04 < W < 1.12$ (gpg)	[Last Modified Fri Dec 17 15:21:41 2004 (GMT)]
22. root code to extract altp (gpg)	[Last Modified Wed Jun 22 02:15:12 2005 (GMT)]
23. tests of ALTp algorithms (gpg)	[Last Modified Fri Dec 24 12:59:56 2004 (GMT)]
24. RC for JL (gpg)	[Last Modified Wed Nov 24 18:46:06 2010 (GMT)]
25. R&A momentum corrections (gpg)	[Last Modified Thu Feb 3 04:17:23 2005 (GMT)]
26. R&A corrections 2 (gpg)	[Last Modified Wed Feb 16 00:12:12 2005 (GMT)]
27. R&A corrections 3 (gpg)	[Last Modified Thu Feb 17 21:04:47 2005 (GMT)]
28. Don't use xB for quasi-elastic scattering (Gerard P Gilfoyle)	[Last Modified Thu Feb 17 22:00:40 2005 (GMT)]
29. Effect of electron fiducial cuts. (GPG)	[Last Modified Wed Feb 23 00:05:23 2005 (GMT)]
30. ALTp at $p_m = 0.0$ (gpg)	[Last Modified Mon Feb 21 04:31:16 2005 (GMT)]
31. checking p_m spectra (gpg)	[Last Modified Fri Mar 4 05:06:47 2005 (GMT)]
32. theta vs phi e in p_m bins (gpg)	[Last Modified Wed Feb 23 18:35:00 2005 (GMT)]
33. Tighter efid cuts (gpg)	[Last Modified Wed Feb 23 22:04:48 2005 (GMT)]
34. More tests of missing momentum (gpg)	[Last Modified Mon Mar 14 03:47:01 2005 (GMT)]
35. Electron Fiducial Dependence of ALTp (GPG)	[Last Modified Thu Mar 17 21:47:35 2005 (GMT)]
36. Talk for CLAS feb, 2005 meeting (gpg)	[Last Modified Sun Mar 20 20:26:44 2005 (GMT)]
37. more comparisons of ALTp to study electron fiducials effect (gpg)	[Last Modified Tue Jan 10 19:55:34 2006 (GMT)]
38. codes for determining electron fiducials (gpg)	[Last Modified Mon Mar 28 16:48:40 2005 (GMT)]
39. More tests on ALTp (gpg)	[Last Modified Fri Apr 8 16:25:31 2005 (GMT)]
40. The low Q2 anomaly (gpg)	[Last Modified Fri May 13 04:11:57 2005 (GMT)]
41. running excludad for JL (gpg)	[Last Modified Fri Jun 10 14:55:38 2005 (GMT)]
42. First proton fiducial look (gpg)	[Last Modified Mon May 9 19:34:56 2005 (GMT)]
43. Second (and third) look at proton fiducials (gpg)	[Last Modified Mon May 16 14:28:33 2005 (GMT)]
44. Comparison with quasielastic events (gpg)	[Last Modified Tue May 17 03:28:25 2005 (GMT)]
45. Excluding more quasielastic events (gpg)	[Last Modified Fri May 20 18:19:23 2005 (GMT)]
46. Including positive pions with the ep events (gpg)	[Last Modified Thu Jun 9 21:23:40 2005 (GMT)]
47. S1 2-3 gen hadron fiducial fits (gpg)	[Last Modified Mon Jun 6 19:10:07 2005 (GMT)]
48. 3rd look at proton/hadron fiducials (gpg)	[Last Modified Thu Jun 2 23:18:58 2005 (GMT)]
49. s2 2-3 gen hadron fiducial fits (gpg)	[Last Modified Mon Jun 6 20:32:20 2005 (GMT)]
50. S3 2-3 gen fits (gpg)	[Last Modified Thu Jul 28 12:54:16 2005 (GMT)]
51. Code for acceptance plots (gpg)	[Last Modified Fri Jun 3 13:51:15 2005 (GMT)]
52. S4 2-3 gen fits (gpg)	[Last Modified Tue Jun 7 01:21:35 2005 (GMT)]
53. S5 gen 2-4 plots (gpg)	[Last Modified Tue Jun 7 01:25:57 2005 (GMT)]
54. S6 gen 2-3 fits (gpg)	[Last Modified Tue Jun 7 17:16:11 2005 (GMT)]
55. effect of proton fiducial cuts and ALTp at 2.6 GeV, normal polarity (gpg)	[Last Modified Sun Jan 1 14:40:30 2006 (GMT)]
56. plots for Collaboration meeting talk (gpg)	[Last Modified Fri Jun 10 18:57:56 2005 (GMT)]
57. Effect of neutron cuts on ALTp (gpg)	[Last Modified Wed Jun 22 14:12:25 2005 (GMT)]
58. plot of Arenhoevel curves (gpg)	[Last Modified Wed Jun 15 02:48:14 2005 (GMT)]
59. another study of electron fiducial cut effects (gpg)	[Last Modified Wed Jun 15 13:51:02 2005 (GMT)]
60. Rusty's results for momentum corrections at 2.6 GeV, reversed polarity (gpg)	[Last Modified Tue Jun 21 10:40:07 2005 (GMT)]
61. stuff for JML (gpg)	[Last Modified Thu Jun 23 03:19:52 2005 (GMT)]
62. KG reversed polarity efid (gpg)	[Last Modified Thu Jun 23 20:01:21 2005 (GMT)]
63. 2.6r pcorr1, Pitt method (gpg)	[Last Modified Wed Jul 6 15:44:00 2005 (GMT)]
64. MM2 for e'pi+X for Pitt method (gpg)	[Last Modified Sun Jul 3 16:46:03 2005 (GMT)]
65. VB p e corrections for 2.6r (gpg)	[Last Modified Tue Jul 5 15:27:35 2005 (GMT)]
66. ALTp for 2.6r (gpg)	[Last Modified Fri Feb 3 20:04:58 2006 (GMT)]
67. Acceptance for OE events for 2.6r (gpg)	[Last Modified Wed Jul 6 18:24:12 2005 (GMT)]

68. [\[ML curves \(gpg\)\]](#) [Last Modified Fri Sep 2 19:32:59 2005 (GMT)]

Jerry Gilfoyle's Enotebook page 1 - test (Jerry Gilfoyle)

[Modified Wed Nov 4 16:14:02 2009 (GMT) Jerry Gilfoyle]

test

test again.

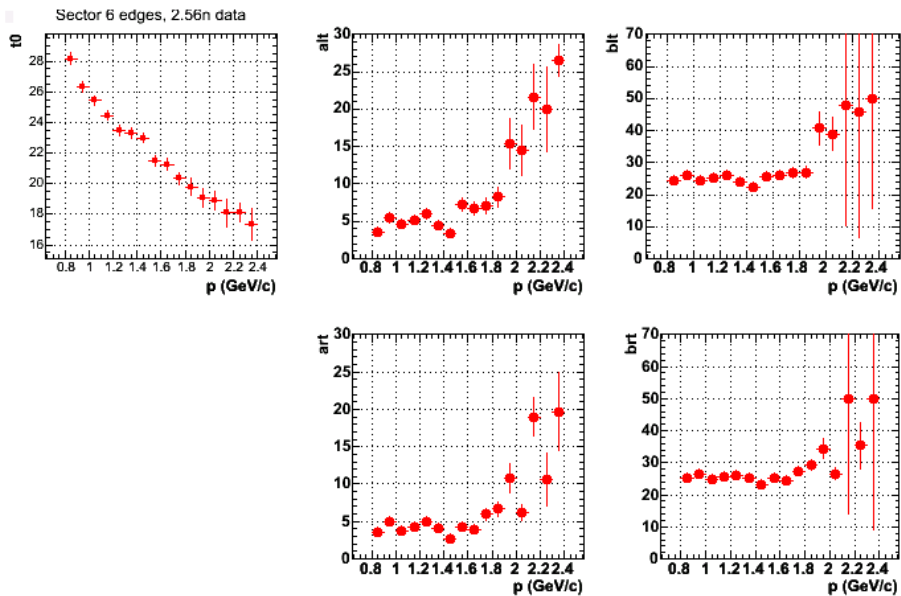

Jerry Gilfoyle's Enotebook page 2 - sector 6 2gen fits (gpg)

[Modified Thu Jun 2 11:17:28 2011 (GMT) gpg]

the second generation fits for sector 6 initially look quite bad, there are many points that lie far from the trend of most of the data. see plot in paper notebook, see entry 234 in e5 elog. remove the following angular points.

pbin	thetabin
8	33 42 43
9	32 41 42
10	30 31 40 41
11	30 40 41
12	29 39 40
13	28 29 39 40
14	27 28 38 39
15	27 38 39
16	27 38 39
17	26 27 38 39
18	26 38 39 40
19	25 26 36 37
20	25 26 35 36
21	25 26 31 32
22	25 29 30
23	24 25

Click [here](#) to view the object (2nd generation fits with points removed.) you uploaded.

Systematics of sector 3 fit parameters.

Jerry Gilfoyle's Enotebook page 7 - sector 2 results (gpg)

[Modified Thu Jul 29 17:26:01 2004 (GMT) gpg]

the sector 2 2gen fit results are below. this sector appears to have lots of holes. the results below are after cleaning up fits for pbins=11-13. see paper log for original.

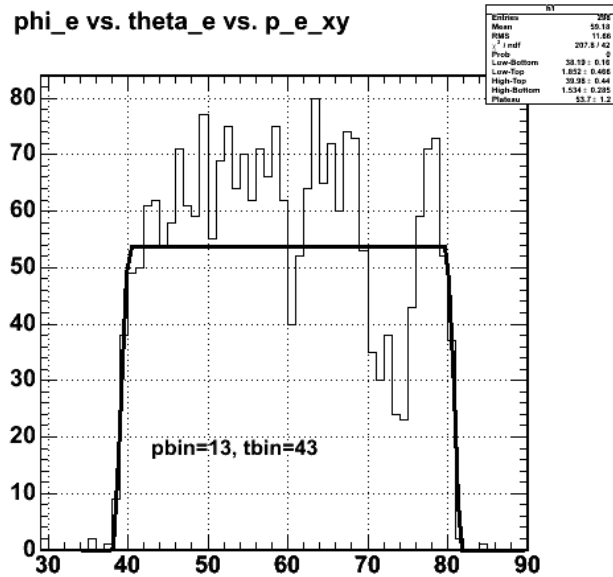

Click [here](#) to view the object (sector 2gen fits) you uploaded.

2004-07-22 10:09:48

Sector 2, theta-e vs. phi_e

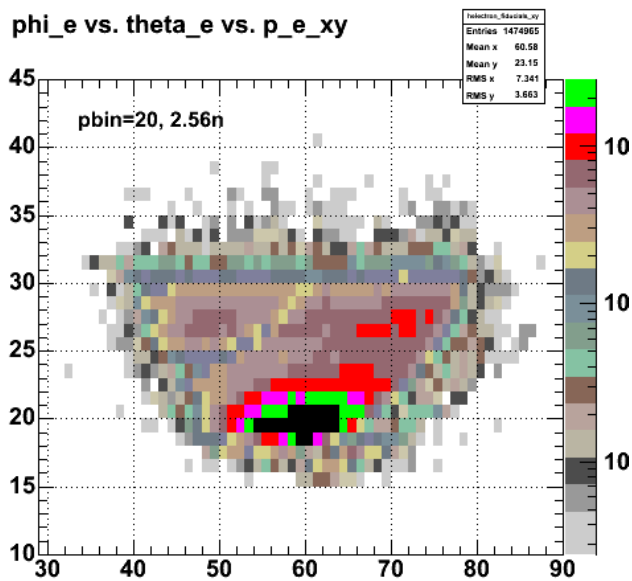

an example of one hole is shown below.

2004-07-22 10:18:05

sector 2, pbin=13, tbin=43. note hole

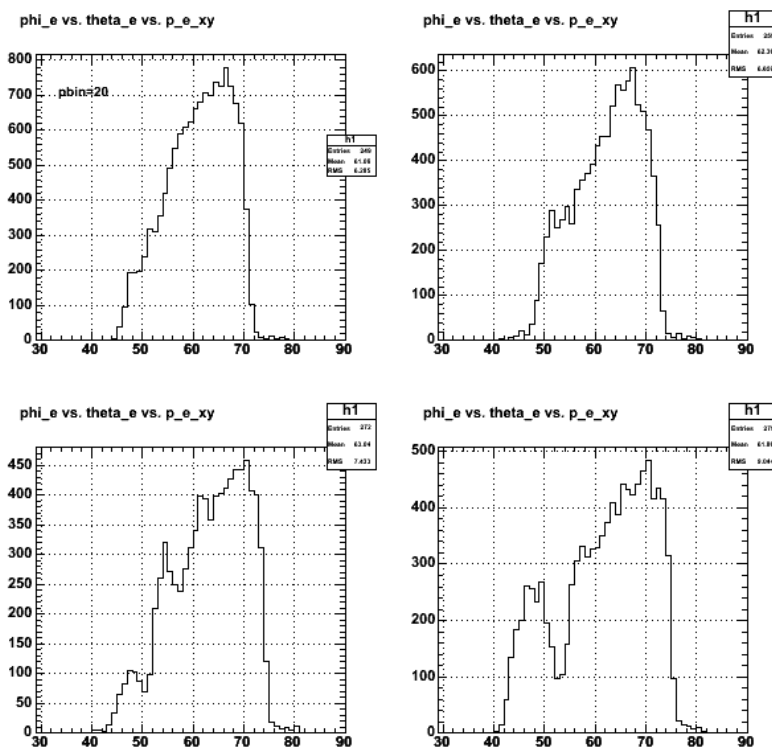

the holes get worse at higher electron momentum.

2004-07-29 11:08:16

Electron singles at p=2.0 GeV/c

the plot below for pbin=20 (p_e=2.0-2.1 GeV/c) shows how the hole destroys the flat region of the acceptance for much of the phi range and then gradually recedes.

Series of phi_e distributions showing the effects of holes in the acceptance.

the question now is how do we handle these regions. do we delete them entirely, figure out the edge of the acceptance by eye. for example, in the plot above we could make the low-phi_e angle edge the following values:

tbin	low phi _e edge	uncertainty
23	48	2
24	50	2
25	48	2
26	47	2

Thu Jul 29 13:18:25 2004

Systematics for sector 2, 2.56n

The last two points in the plot above should be ignored because the dominant feature of the phi distribution is a hole. See plot below. Many of the edges for the low phi_e part simply could not be fit so i just eyeballed the 'flat' region.

Click [here](#) to view the object (Last four momentum bins or sector 2, 2.56n.) you uploaded.

Jerry Gilfoyle's Enotebook page 8 - momentum corrections 1 (gpg)

[Modified Tue Aug 3 13:30:35 2004 (GMT) gpg]

Using the method described by Jeff Lachniet in entry [109](#) Rusty and Artie have been trying to reproduce Jeff's results for the momentum corrections. Rusty has found initially that the overall difference between the measured momentum and the momentum of the electron calculated from its polar angle is very small (about 0.1% , the ratio of measured to calculated is 1.001). The standard measure is to use the $e\bar{p} \rightarrow e\pi^+X$ reaction, calculate the missing mass which should be dominated by the neutron, and compare the result with the neutron momentum. Rusty's finds the average MM for a single 2.56n run using the measured momentum is 0.935 GeV (versus the accepted value of 0.9396 GeV). This is a difference of 0.4% which is much larger than the momentum difference. The corrected momentum changes the MM very little. I have taken a look at the ratio of measured to calculated momentum and generated the plot below for the 2.56r data.

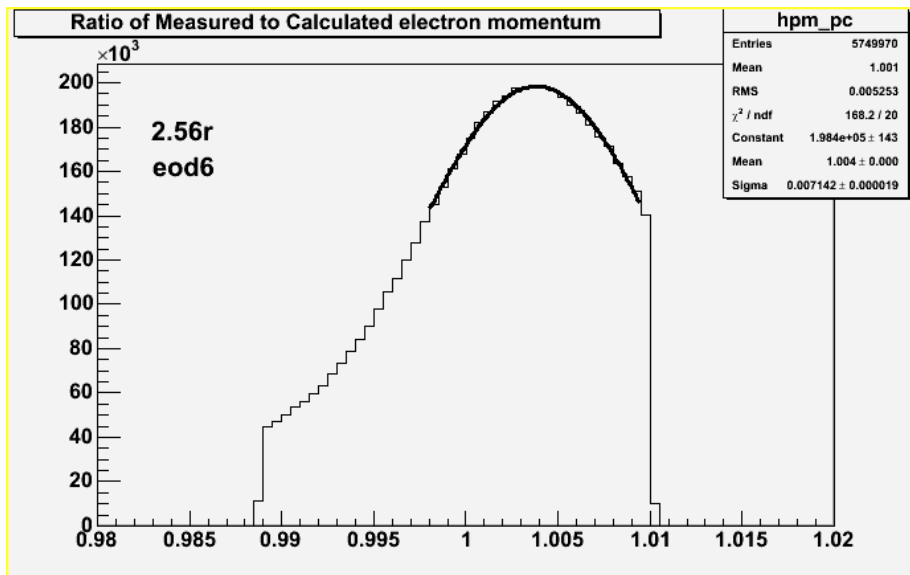

Figure 1. Ratio of measured electron momentum to electron momentum calculated from the measure track angles for the 2.56r data set.

Here, looking at a large data set the difference in the momentum is about 0.4% which agrees with the difference between the missing mass determined with the measured electron momentum.

Figure 2 is a sample plot demonstrating use of profile histograms and projections. We are having a problem with the profile histograms when we get single data points that have unphysical values, but get weighted the same as other values. See the plots below. Upper left panel of Figure 2 is the original 2D histogram. Upper right is the profile histogram made from the 2D. Note the point at a position (0.4,0.07). This is greatly different from the rest of the points. The lower left panel shows a projection of the 2D on the horizontal axis. Notice the point at 0.4 has a single count in it while the others are over a thousand. The plan here is to test on each bin to make sure there is some minimum number of points like, say, 50. If this threshold is not exceeded we throw the point out by setting the bin contents for the profile histogram for that bin to zero. The lower right panel of the next figure, Figure 3 and plots below (Figure 4) show what happens when we do that and then fit the results.

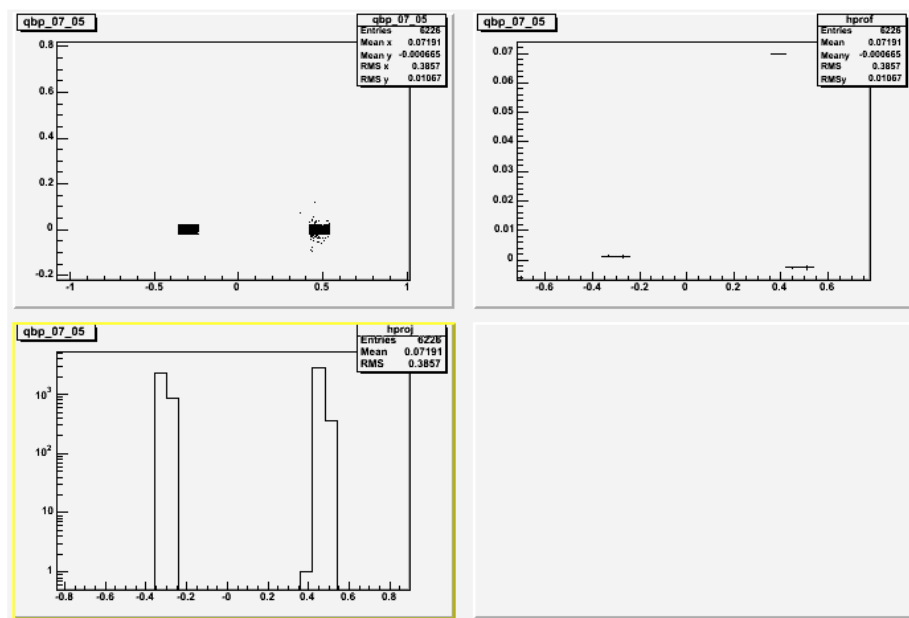

Figure 2. Examples of 2D, profile, and projection histograms.

The code below is the set of Root commands used to generate the histograms in Figure 2-4.

```

root [1] TProfile *hprof = qbp_07_05->ProfileX("hprof")
root [2] hprof.Draw()

Jerry Gilfoyle's Enotebook page 11 - testing fiducial function (gpg)

[Modified Mon Aug 30 18:11:09 2004 (GMT) gpg]

The fiducial cuts described in entries [228](#), [234](#), [235](#), and [236](#) are tested below for the first time. The statistics are very limited because the fileserver is busted and I am waiting for a replacement.

Fig 1. Testing new 2.56n electron fiducial cut.

The C++ routine is shown below.

```
Int_t eod5::DPelectron_fiducial_cut26n(float Phi_curr, float P_curr, float theta_e)
{
// This function may be called from Loop. it returns 1 if the electron theta and phi
// lie within the fiducial volume. it returns 0 otherwise.
//
// inputs.
int sector, good_p, good_phi;
float t0, alt, blt, art, brt, theta_curr, pmin, pmax, phi_min, phi_max;

// read in the 3gen fit parameters.

float t0_pars[6][5] = {
1, 0.8, 2.4, 26.9529, -0.406995,
2, 0.8, 2.2, 26.9709, -0.439026,
3, 0.8, 2.4, 25.9509, -0.442319,
4, 0.8, 2.4, 26.159, -0.429777,
5, 0.8, 2.4, 26.1886, -0.436065,

Jerry Gilfoyle's Enotebook page 12 - SJ calculations at 12 GeV (GPG)

[Modified Sat Jul 23 16:57:06 2011 (GMT) GPG]

As a first look at things at 12 GeV, I have used Sabine's code to calculate $rtlp$, the response function associated with ALTP at 'low' quasielastic kinematics ($E=2.56$ GeV, $Q^2=1.0$ GeV²) and 'high' kinematics ($E=12$ GeV, $Q^2 = 10$ GeV²). There is a decrease in $rtlp$ of about a factor of 10 or so. this may mean that measuring ALTP may not be feasible after the upgrade. It will depend on the actual increase in the luminosity that CLAS++ can handle.

It's worth noting a surprise for me. The RL response rl is large as expected, but rt is small and rtl is very large. I expected rt to be comparable to rl and rtl to be small. Do we understand this???

Also SJ seemed to imply in our phone conversation that rl and rt should not drop much at the higher Q^2 , but in these plots they high- Q^2 ones are smaller by a factor of 20??

Mon Sep 6 10:24:12 2004

W2 vs. ϕ_e

2004-11-17 14:40:54

Fig 3. W^2 versus ϕ for the corrected electron momentum.

PS plot [here](#) of W^2 proton peak for corrected electron momentum sector-by-sector.

PS plot [here](#) of W^2 proton peak for uncorrected electron momentum sector-by-sector.

The improvement in the position and width of the elastic peak is shown in the table below sector by sector. The fourth column (labelled %diff) is the percentage difference between the 'after' centroid and the expected value. For comparison I also show Jeff's results that he obtained previously from the same [analysis](#). The two analyses agree within a fraction of a percent. The final column shows the percent difference between the improved centroids for Jeff and me.

Sector	centroid (0.8804 expected)			JL centroid		
	before	after	%diff	before	after	%diff (JL-GPG)
1	0.8682	0.8790	0.16	0.8731	0.8784	0.07
2	0.8355	0.8767	0.42	0.8323	0.8697	0.80
3	0.8940	0.8808	0.05	0.8819	0.8838	0.34
4	0.8711	0.8791	0.15	0.8669	0.8763	0.32
5	0.8729	0.8793	0.12	0.8606	0.8734	0.67
6	0.8850	0.8807	0.03	0.8766	0.8809	0.02

Average improvement in the W^2 peak position is only about 1%, but sector 2 improves by about 5%.

Sector	width	
	before	after
1	0.03557	0.02789
2	0.04839	0.02699
3	0.03346	0.02800
4	0.03126	0.02781
5	0.03332	0.02870
6	0.03006	0.02957

Average improvement in the width of proton peak in the W^2 spectrum is about 20%.

Jerry Gilfoyle's Enotebook page 16 - recent ALTp results (gpg)

[Modified Wed Nov 24 17:09:10 2004 (GMT) gpg]

Fig 1. ALTp for 2.6n, all Q^2

Fig 2. Q^2 distribution for ALTp in Figure 1.

Fig 3. Quasielastic cut applied to ALTp in Figure 1.

Jerry Gilfoyle's Enotebook page 17 - ALTP with and without electron fiducial cuts at 2.6n (gpg)

[Modified Wed Jan 11 01:23:11 2006 (GMT) gpg]

Below is a comparison of ALTP averaged over the full Q^2 range for the 2.56, normal-polarity run. The black points are from the analysis with the new electron fiducial cuts described [here](#) and the new momentum corrections. The red points have the new fiducial cuts turned off and the new momentum corrections turned on. It is disturbing that the two significant excursions from zero in ALTP with the new fiducial cuts disappear when the new cuts are turned off.

Fig 1. Comparison of A_{LT}' with (black) and without (red) the latest electron fiducial cuts.

To view the Root file used to create the above plot, click [here](#).

The plot below shows the same stuff as above, but now I include A_{LT}' with no momentum corrections and no electron fiducial cuts. surprisingly, this looks the best. It is small for p_m close to zero, the third bin isn't way below the adjacent bins, the eighth bin isn't way below its neighbors, and it's consistent with the no electron fiducial cuts plus new momentum corrections at the other points. Why did I even bother????!! This is a mystery to me.

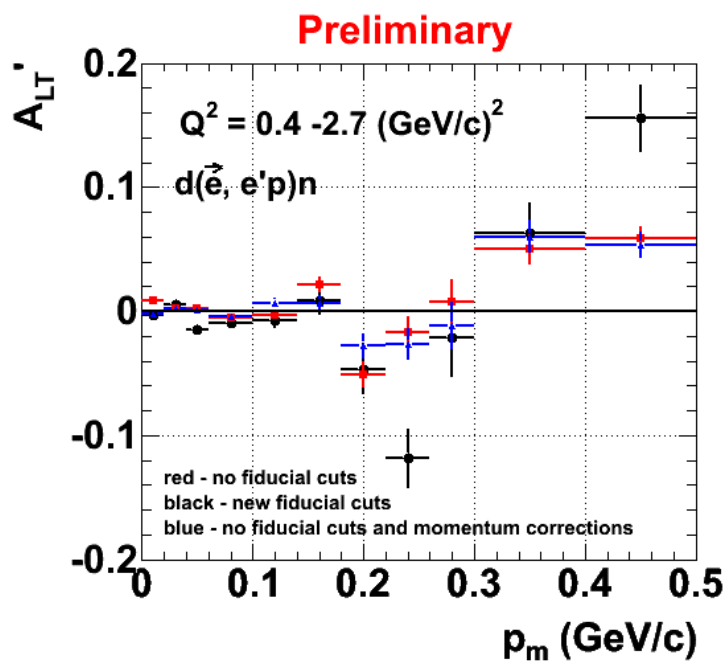

Fig 2. Same as Figure 1 with the momentum corrections off and electron fiducials off.

Now look at turning the new fiducial cuts on with the momentum corrections off.

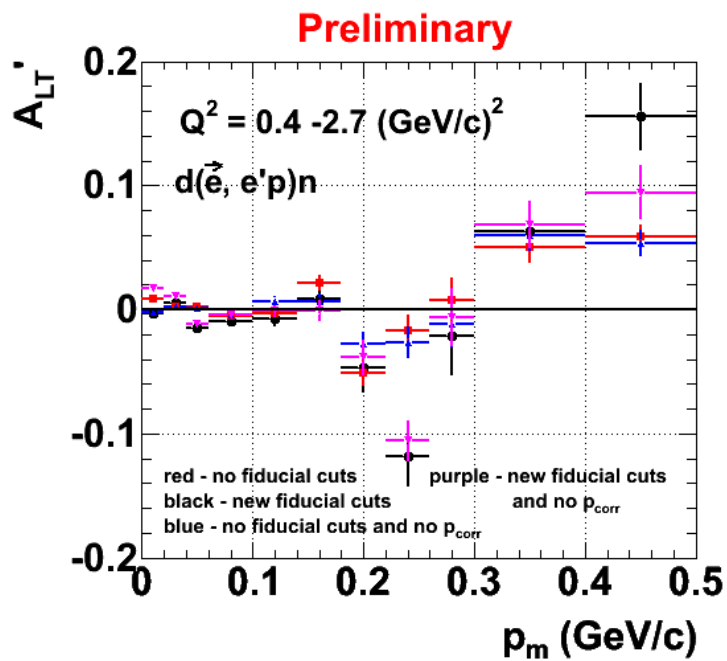

Fig 3. Same as Figure 2 with purple points for new fiducial cuts on and momentum corrections off.

The plot below shows A'_{LT} for a variety of conditions. The Root macro to create the plot is [here](#). I have started looking at the dependence on the cut defining a quasielastic event. The original cut for the plots above was $0.912 < W < 0.966$. In the results shown below for the expanded quasielastic cuts low means $W > 0.80$ and high means $W < 1.0$.

Fig 4. More comparisons of A_{LT} with different cuts.

Jerry Gilfoyle's Enotebook page 18 - ALTp comparison with different Quasielastic cuts (gpg)

[Modified Wed Dec 1 16:20:34 2004 (GMT) gpg]

The plot below shows a comparison of ALTp for different W cuts to define quasielastic events. The original cut for the plots above was $0.912 < W < 0.966$. In the results shown below for the expanded quasielastic cuts low means $W > 0.80$ and high means $W < 1.0$. What is mysterious to me is the large dip at $p_m = 0.24$ GeV/c for a narrow W cut which largely disappears when the W cut is lowered. This surprises me because I made the QE cut narrow to get above any background leaking in from the resonance region. I thought letting the QE cut extend to lower W would not contaminate the QE events. Does the background from the resonance region extend down that far in W?

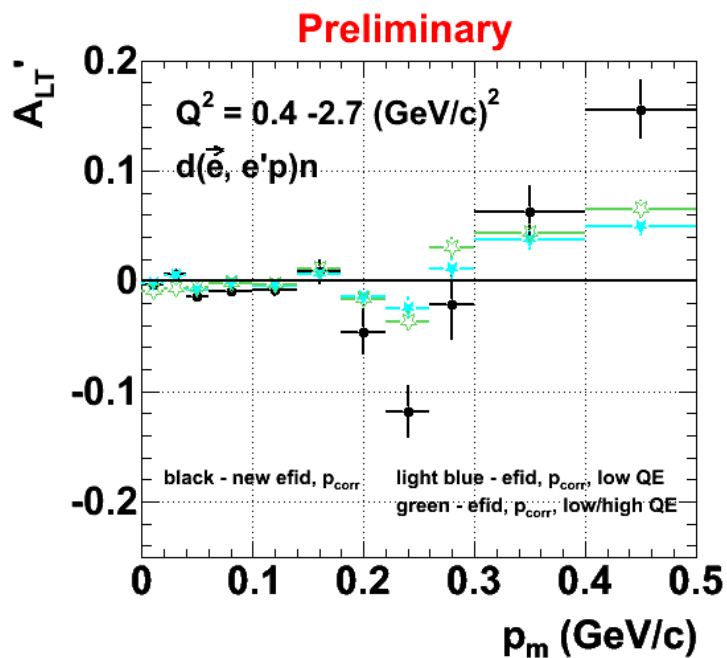

Fig 1. Comparison of ALTp using different W cuts to define quasielastic events.

Fig. 2 W spectrum for 2.56n run. Red lines show original, tight W cut for defining quasielastic events.

Jerry Gilfoyle's Enotebook page 19 - selecting QE events (gpg)

[Modified Thu Dec 9 13:28:43 2004 (GMT) gpg]

Some plots below to improve quasielastic event selection. Since I'm now using a wide Q2 bin, i need to think about more careful selection of QE events. My first thought would be to apply a coplanarity cut to the data since the proton and neutron should come out in the same plane.

Electron-Proton Opening Angle versus W

2004-12-03 13:56:32

Fig 1. Electron-proton opening angle.

Plot below shows the effect of adding a cut on the angle between the virtual photon 3-momentum and the 3-momentum of the ejected proton. This is the cut Jeff uses on the Gmn analysis. The points beyond $p_m \sim 0.22$ GeV/c have very large asymmetry, but also huge uncertainties.

Fig 2. ALTp with an addition cut on the angle between the virtual photon and the ejected proton.

Results for plot below are in QEcute1.root.

Fig 3. Effect of different cuts on the W^2 spectrum.

Fig 4. Test of effect of gamma-theta_{pq} cut.

Jerry Gilfoyle's Enotebook page 20 - More tests of efid and pcorr (gpg)

[Modified Wed Dec 15 16:28:20 2004 (GMT) gpg]

More tests of the new electron fiducial cuts and electron momentum corrections. These are based on the quasielastic cut $0.8 \text{ GeV}^2 < W < 1.0 \text{ GeV}^2$.

Fig 1. Comparison of AL_T for different sets of cuts and corrections.

Root file to produce the plot above is [here](#).

WKB suggests looking at the changes in AL_T across the quasielastic peak in the W spectrum. The first such plot is shown below for a W bin 1.00-1.04 GeV. The statistics are bad so use a bigger bin next time.

2004-12-10 15:28:28
 Fig 2. ALTp with p_{corr} and efid both turned on and the quasielastic cut is defined at 1.0 < W < 1.04.

A C++ file with the data in it is [here](#).

Jerry Gilfoyle's Enotebook page 21 - high ALTp point for $1.04 < W < 1.12$ (gpg)

[Modified Fri Dec 17 15:21:41 2004 (GMT) gpg]

There is an anomalously high value of ALTp for the $1.04 < 1.12$ spectrum that is worth investigating. The figure below shows the $\sin(\phi_{pq})$ weighted spectra for positive and negative helicities. Notice the high point in the third p_m bin for the positive helicity spectrum.

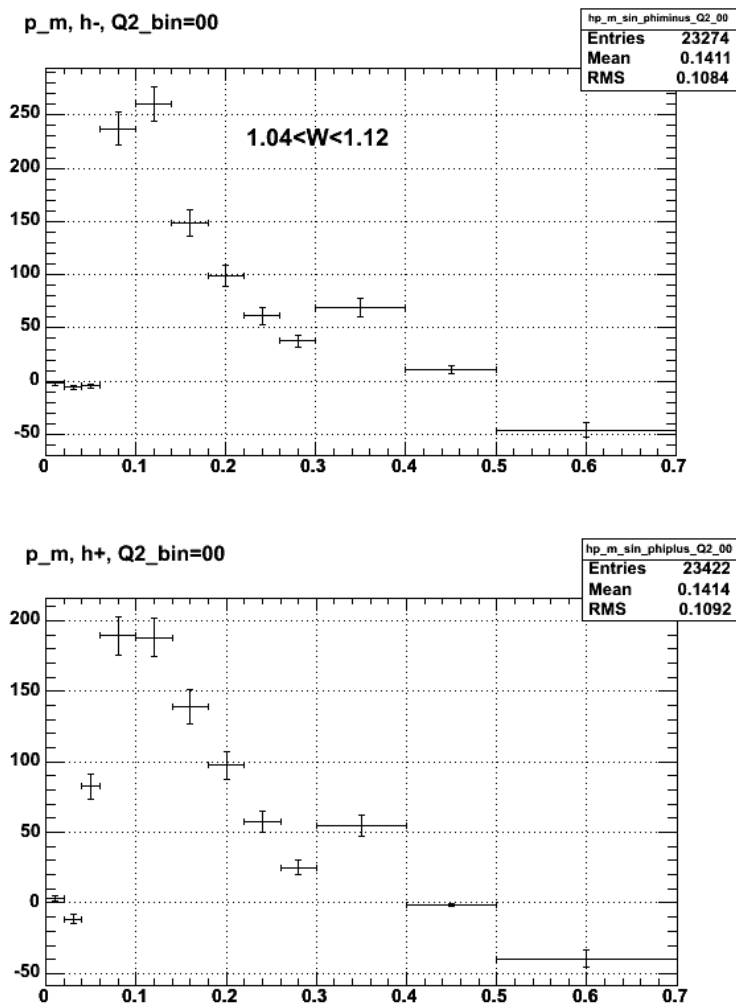

Fig 1. $\sin(\phi_{pq})$ weighted histograms.

Look at the unweighted spectra below. For the third bin, the number of counts looks very similar.

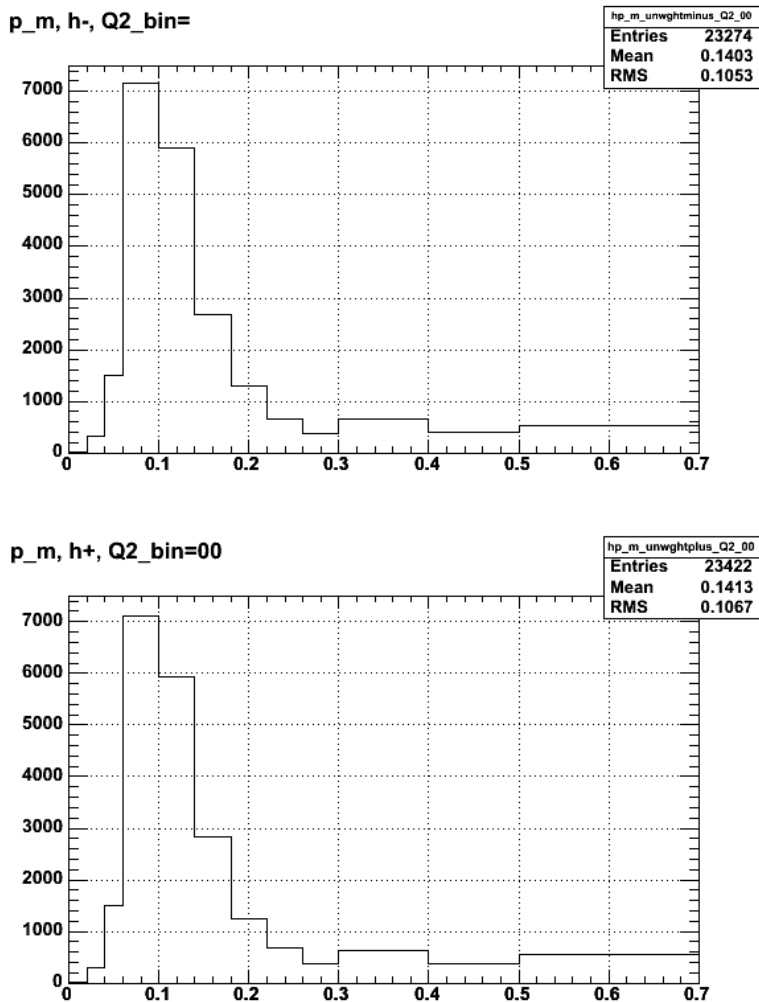

Fig 2. Same as above except for unweighted spectra.

Look at the helicity asymmetry.

Jerry Gilfoyle's Enotebook page 22 - root code to extract altp (gpg)

[Modified Wed Jun 22 02:15:12 2005 (GMT) gpg]

The code used to extract ALTP from the sin(phi_pq) weighted spectra is below.

```
int n_varp_mbins = 12;
Float_t p_m_bin_edges[13]={0.0,0.02,0.04,0.06,0.10,0.14,0.18,0.22,0.26,0.30,0.40,0.50,0.70};
TH1F *h1a = new TH1F("h1a","Sin(#phi) weighted distribution for positive helicity",n_varp_mbins,p_m_bin_edges);
TH1F *h2a = new TH1F("h2a","Sin(#phi) weighted distribution for negative helicity",n_varp_mbins,p_m_bin_edges);
h1a.Sumw2();
h2a.Sumw2();
h1a.Divide(hp_m_sin_phiplus_Q2_00, hp_m_unwghtplus_Q2_00);
h2a.Divide(hp_m_sin_phiminus_Q2_00, hp_m_unwghtminus_Q2_00);
TH1F *h12a = new TH1F("h12a","A_{LT}'",n_varp_mbins,p_m_bin_edges);
h12a.Sumw2();
h12a.Add(h1a,h2a,1.0,-0.9994);
h12a.Draw();
```

The code below is a modified version of the stuff above that includes the correction for the average polarization.

```
int n_varp_mbins = 12;
Float_t p_m_bin_edges[13]={0.0,0.02,0.04,0.06,0.10,0.14,0.18,0.22,0.26,0.30,0.40,0.50,0.70};
TH1F *h1a = new TH1F("h1a","Sin(#phi) weighted distribution for positive helicity",n_varp_mbins,p_m_bin_edges);
TH1F *h2a = new TH1F("h2a","Sin(#phi) weighted distribution for negative helicity",n_varp_mbins,p_m_bin_edges);
h1a.Sumw2();
h2a.Sumw2();
h1a.Divide(hp_m_sin_phiplus_Q2_00, hp_m_unwghtplus_Q2_00);
h2a.Divide(hp_m_sin_phiminus_Q2_00, hp_m_unwghtminus_Q2_00);
TH1F *h12a = new TH1F("h12a","A_{LT}'",n_varp_mbins,p_m_bin_edges);
h12a.Sumw2();
h12a.Add(h1a,h2a,1.0,-0.9994);
h12a.Multiply(1.35);
h12a.Draw();
```

Code below is for getting the helicity asymmetry as a function of phi_pq. These results are then fitted with a sine curve to get the amplitude which should agree with the results from the sin(phi_pq)-weighted analysis using the code just above.

```
Int_t n_varp_mbins = 12;
Double_t p_m_bin_edges[13]={0.0,0.02,0.04,0.06,0.10,0.14,0.18,0.22,0.26,0.30,0.40,0.50,0.70};
TH2F *hphi_p_m_sum = new TH2F("hphi_p_m_sum","#phi_{pq} versus p_{m}, Positive helicity",n_varp_mbins,p_m_bin_edges,9,-180,180);
TH2F *hphi_p_m_diff = new TH2F("hphi_p_m_diff","#phi_{pq} versus p_{m}, Negative helicity",n_varp_mbins,p_m_bin_edges,9,-180,180);
hphi_p_m_sum.Sumw2();
hphi_p_m_diff.Sumw2();
hphi_p_m_sum.Add(hphi_p_m_plus,hphi_p_m_minus,1.0,0.9994);
hphi_p_m_diff.Add(hphi_p_m_plus,hphi_p_m_minus,1.0,-0.9994);
TH2F *hALTP_phi_p_m = new TH2F("hALTP_phi_p_m","A_{LT}^{'} versus p_{m}",n_varp_mbins,p_m_bin_edges,9,-180,180);
hALTP_phi_p_m->Divide(hphi_p_m_diff,hphi_p_m_sum,1.0,1.0);
hALTP_phi_p_m.Draw();
TH1D *hhelicity_asym = (TH1D*) hALTP_phi_p_m->ProjectionY("hALTP_phi_p_m",1,4);
hhelicity_asym.Draw();
```

The stuff above doesn't seem to work because the Add function gives me screwy results when one of the coefficients is negative. Project out the p_m bin first and then do the manipulations. Try the following for starters.

```
gStyle->SetOptStat(00000000)
gStyle->SetOptFit(0001)
Int_t n_varp_mbins = 12;
Int_t pbin=8;
char pbinlabel[3];
sprintf(pbinlabel,"%d",pbin);
TLatex *t1 = new TLatex(-150,-0.1,"pbin=");
TLatex *t2 = new TLatex(-80,-0.1,pbinlabel);
Double_t p_m_bin_edges[13]={0.0,0.02,0.04,0.06,0.10,0.14,0.18,0.22,0.26,0.30,0.40,0.50,0.70};
TH1D *hp_m_bin_plus = hphi_p_m_plus->ProjectionY("hp_m_bin_plus",pbin,pbin);
TH1D *hp_m_bin_minus = hphi_p_m_minus->ProjectionY("hp_m_bin_minus",pbin,pbin);
TH1D *hsum = new TH1D("hsum","summed hists",9,-180,180);
TH1D *hsub = new TH1D("hsub","subtracted hists",9,-180,180);
TH1D *hasym = new TH1D("hasym","(N^{+} - N^{-})/(N^{+} + N^{-})",9,-180,180);
hsum.Sumw2();
hsub.Sumw2();
hasym.Sumw2();
hsum.Add(hp_m_bin_plus, hp_m_bin_minus, 1.0, 0.9994);
hsub.Add(hp_m_bin_plus, hp_m_bin_minus, 1.0, -0.9994);
hasym.Divide(hsub, hsum, 1.0, 1.0);
hasym.SetMaximum(0.2);
hasym.SetMinimum(-0.2);
hasym.Draw("e1");
TF1 *fit1 = new TF1("fit1","[0]*sin(x*0.017453293)",-180,180);
hasym.Fit("fit1","","e0");
t1.Draw();
t2.Draw();
```

Jerry Gilfoyle's Enotebook page 23 - tests of ALTp algorithms (gpg)

[Modified Fri Dec 24 12:59:56 2004 (GMT) gpg]

I wanted to check what I was doing to extract ALTp. This was motivated in part by the anomalously high asymmetry in the top panel of Fig 1 in entry [250](#) at $p_m = -0.05$ MeV/c. I did this by calculating the helicity asymmetry as a function of ϕ_{pq} , fitting it with a sine curve, and comparing my results with the analysis. I noticed that the sine fit was giving similar results to the analysis, but the error bars were bigger by about a factor of 2-2.5. I looked in the code eod5.C where I do the analysis and discovered I had not set the errors for the analysis histograms to use the sum of the squares of the weights instead of the sum of the weights!! When I did this the analysis uncertainties now agree with the sine fits to the helicity asymmetry, but the uncertainties are now twice as large and the structures in ALTp are significantly less significant!!! Damn! Damn! Damn! I am using a quasielastic bin of $0.8 < W < 1.0$ GeV so I will squeeze this down. I talked to Kim E. last week and showed him some of the results from entry [250](#). He makes the point that the counts at high and low W are likely due to inelastic events and I should exclude them from the QE peak.

Fig 1. ALTp with correct uncertainties and wide QE definition integrated over the full Q2 distribution for 2.56n.

I'm going back to check things and I see some inconsistencies. For 2.56n with $QE = 0.88 < W < 1.04$, p_{corr} on, efid on I get the Q2 distribution shown below with 16M events. In a previous entry ([16](#)) the same plot has 27M events. This is a big difference! What is going on? Am I missing files in the analysis run?

Fig 2. Check on Q2 distribution for 2.56n, QE= 0.88 < W < 1.04 GeV, efid on, p_corr on, all Q2.

The new ALTp I get is shown below.

Fig 3. Revised ALTp with 'correct' uncertainties.

The actual values are shown below for the analysis.

Jerry Gilfoyle's Enotebook page 24 - RC for JL (gpg)

[Modified Wed Nov 24 18:46:06 2010 (GMT) gpg]

Below are some plots of the radiative correction curves and surfaces as functions of theta_pq and phi_pq. The kinematics and average radiative correction for the selected region of theta_pq and phi_pq is labeled on each plot. The table below shows the desired kinematics with the average radiative correction shown for protons and neutrons in the last two column. This average radiative corrections is for the given theta_pq (actually the cos(theta_pq)) averaged over phi_pq. The plots show the phi_pq dependence.

At 4.232 GeV beam energy,

Q2	W	theta_pq
0.5	2.0	3.5
1.0	2.13	3.5
1.5	2.24	3.5
2.0	2.35	3.0
2.5	2.45	2.5
3.0	2.55	2.25
3.5	2.65	2.25
4.0	2.74	2.25
4.5	2.83	2.25
5.0	2.92	2.25

At 2.558 GeV beam energy,

Q2	W	theta_pq	average RCp	average RCn
0.25	1.94	4.0	failed - RC's all nan's	
0.5	2.0	4.0		
1.0	2.13	4.0	0.7957	0.7956
1.5	2.24	3.5		
2.0	2.35	3.0	0.8273	0.8273
2.5	2.45	2.75	0.8424	0.8421
3.0	2.55	2.5	0.8583	0.8568

The plots that follow are the results of the analysis of the EXCLURAD output that was further massaged with Mathematica.

$E=2.56$ GeV, $W=2.55$ GeV, $Q^2=3.0$ GeV², $vcut=0.310$ GeV, $\langle RC_p \rangle = 0.8393$

Jerry Gilfoyle's Enotebook page 25 - R&A momentum corrections (gpg)

[Modified Thu Feb 3 04:17:23 2005 (GMT) gpg]

First results from the work of rusty and artie last summer using Jeff Lachniet's first momentum correction method ([entry 109](#)). The plot below shows a comparison of the difference between the electron momentum calculated from the electron angles and the electron momentum from tracking. The right-hand plot is for the electron momentum from tracking corrected using the limited data set that we analyzed with R&S's code last summer. The panel on the left is for the electron momentum directly from tracking with no momentum corrections.

Fig 1. Comparison of difference between the electron momentum calculated from the electron angles and the corrected momentum based on a limited data run

The plot below shows the same quantities, but with the momentum corrections derived from a complete data set run instead of a partial set like Fig 1.

Fig 2.

The plot below shows the same quantities as Fig 2, but the latest version of the electron fiducials is used to select electron events.

Fig 3.

The results below are for the same quantities as the previous figure, but with the momentum correction fit parameters derived from full data set run using the new electron fiducials.

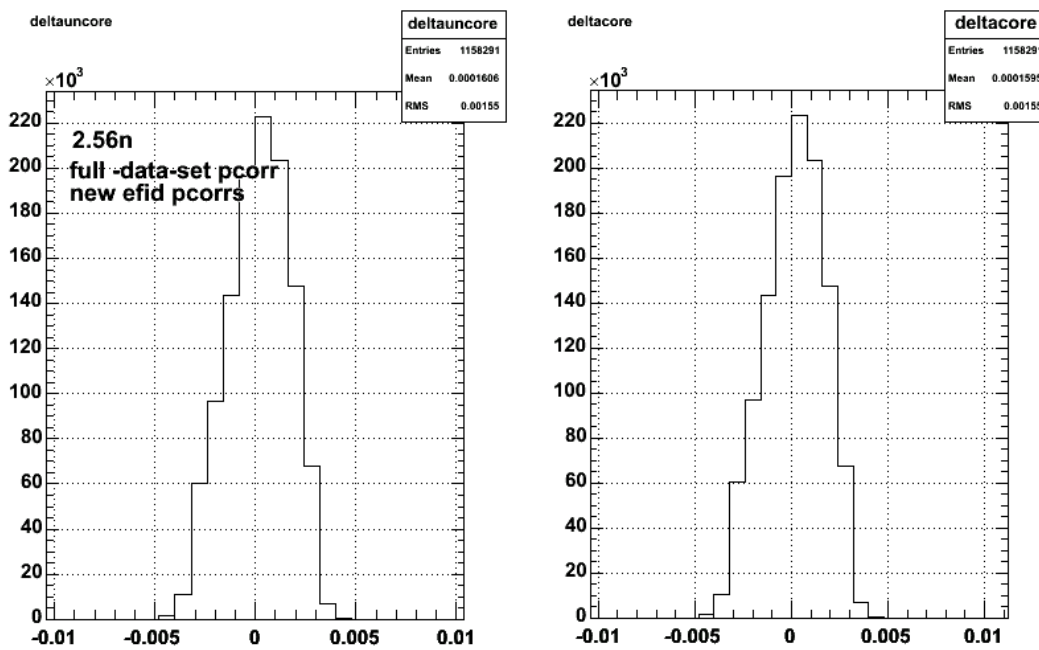

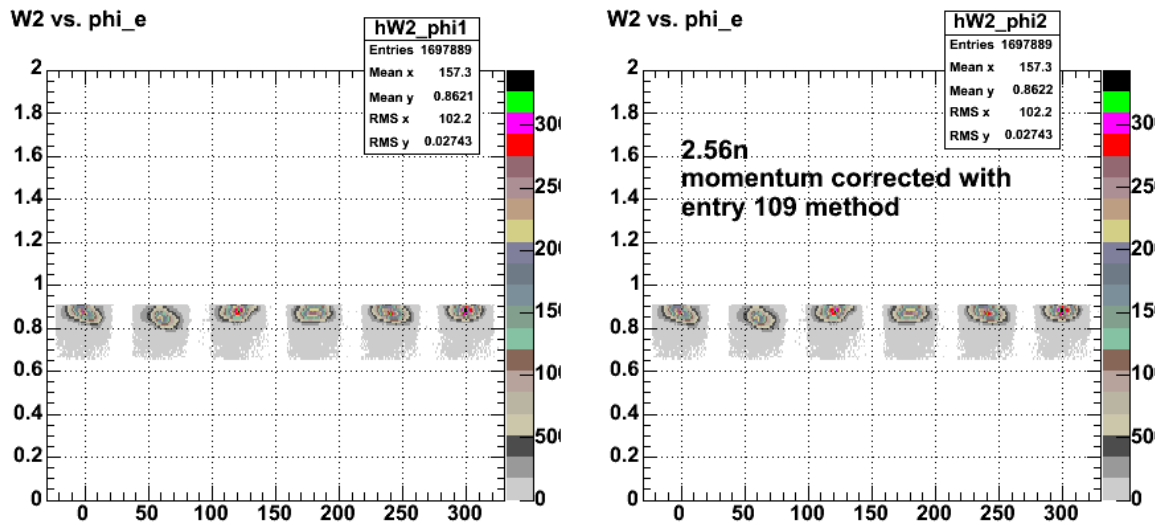

Fig 4. Same as previous plot with momentum correction fit parameters derived from full data set run using new electron fiducials

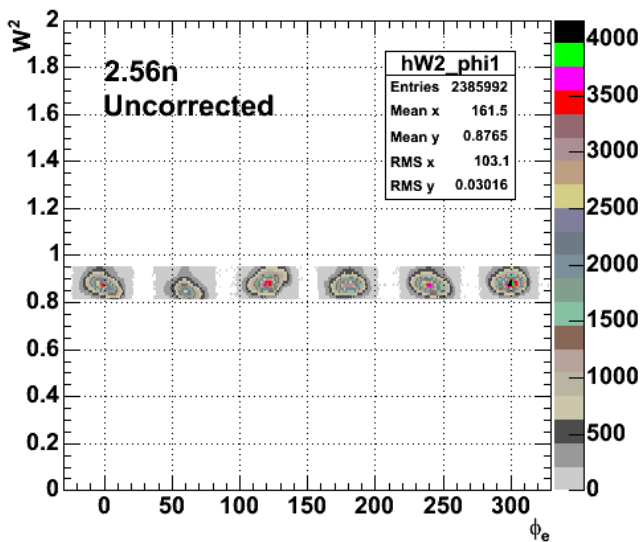

Effect of this momentum correction of W^2 versus ϕ_e

W2 vs. phi_e

Use entry-109 electron momentum correction with ep1.C

W2 vs. phi_e

uncorrected electron momentum with ep1.C

The plot below shows a histogram of the difference between the proton scattering angle calculated from the electron information and the measured proton scattering angle. The uncorrected electron momentum was used to calculate the electron 3-momentum which was then used to get the proton 3-momentum and derive the proton scattering angle. No coplanarity cut was used in this analysis. The 2.56n data set was used.

Histogram of difference between proton angle calculated from the electron information and the measured one.

The plot below shows the coplanarity distribution. This is the azimuthal angle between the scattered electron and the proton. From this plot it's clear that there are few non-elastic events. Nevertheless, I will set $180 > \phi_{cop} > 179.5$ to see if there is any effect on the event selection and on the difference between the measured proton scattering angle and the proton scattering angle calculated from the electron data.

Histogram of co-planarity angle.

Plot below shows a test of the effect of a cut on the coplanarity angle on the difference between the scattering angle of the proton calculated from the electron results and the scattering angle of the proton from tracking. There is little change in the shape of the distribution. About 25% of the events are lost uniformly across the distribution.

Difference between proton scattering angle calculated from the electron results and from tracking. Cut on coplanarity is required.

Click [here](#) to view the object (Profiles of d(curvature) for qbp_00_05) you uploaded.

The results below are for R&A analysis where I required that the coplanarity angle lie in the range 179.7->180.0 and the difference between the measured proton scattering angle and the one calculated from the electron results was in the range -0.02 deg -> 0.5 deg. These limits are based on the results above. Plot below shows delta(qB/p) versus qB/p for one of the bins in sector 2. Things to notice in comparison with the work in CLAS-Note 2001-018 is that the vertical range of the data is much smaller in our case. In the CLAS-Note they plot their results on the same large scale as shown in the figure below. This is to emphasize that the E5 data are in better shape after cooking than the e1b/c data.

qbp_09_06

D(qB/p) versus qB/p for 2.56n run showing small deviation in the curvature from the calculated result

qbp_10_06

Same as above for sector 3 bin

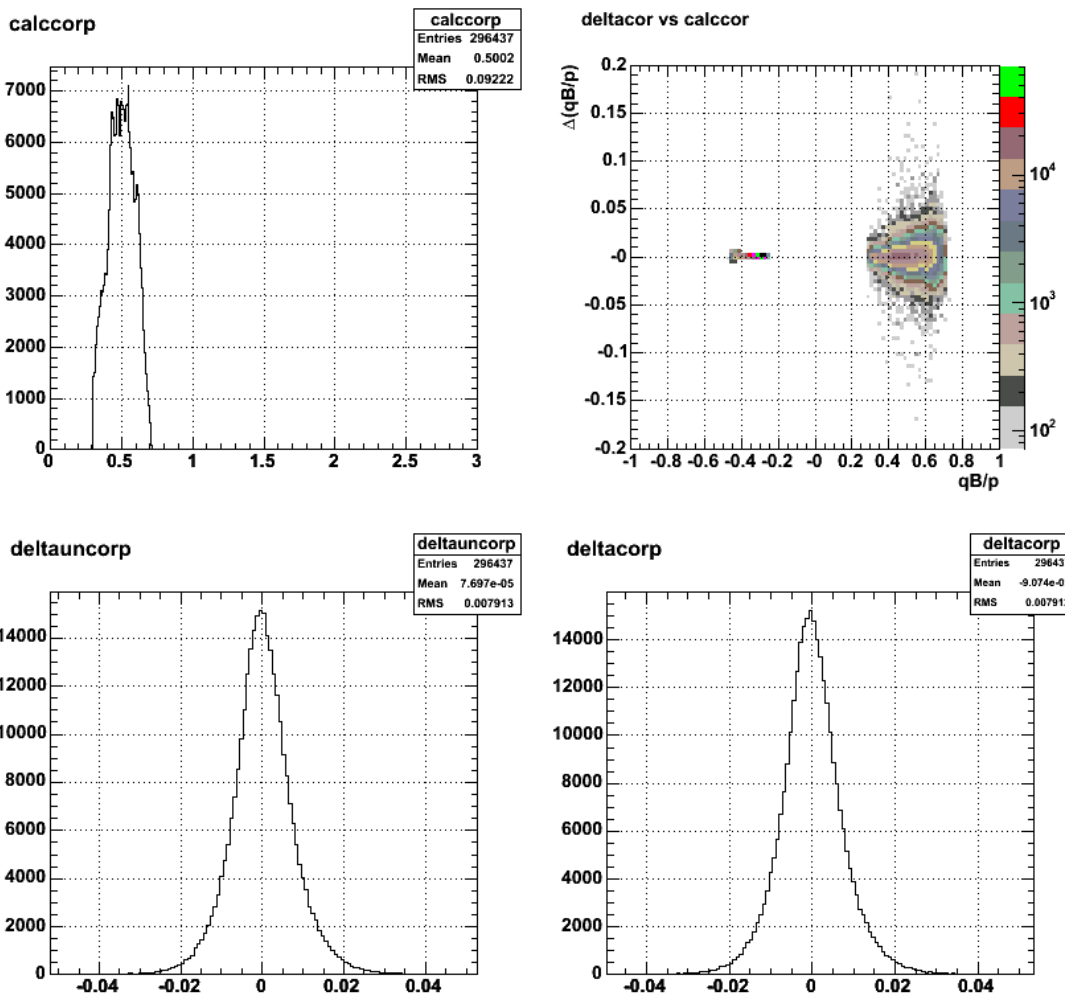

The plot below shows $\Delta(qB/p)$ versus qB/p for all angle bins lumped together. The point here is that the width of the distribution of the protons is far greater than the width of the distribution of the electrons. This would explain the small effect of the correction on W since we're dominated by the deviation of the proton momentum from the calculated value and the electron curvature deviation is small. What is mysterious to me about the plot below is the magnitude of width is huge (about a factor of 10) greater than the individual variations I see in a given bin. I may just be deceiving myself with the statistics of the plots for individual bins and the effect of the use of a logarithmic axis in the z direction in the plot below.

deltacor vs calccor

Same as above for all angle bins lumped together

One thought I had was that even though this approach seems to have little effect on the electrons, perhaps it could be used to correct the proton momentum. Unfortunately, that doesn't seem to work either. The plot below shows before and after pictures in the lower two panels of the difference between the expected proton momentum (using the measured scattering angles) and the measured one (left is uncorrected, right panel is corrected). There is no difference between the before and after picture in mean or RMS. There is no significant improvement even in the proton results.

lots showing proton results before and after corrections for the protons

To close the loop I generated a new set of parameters to correct the electron and proton momenta using the entry-109 method. This last set was generated from data that had the coplanarity cut ($179.7 < \theta_{cop} < 180$) and θ_p cut ($-0.2 < \theta_{p_from_e} - \theta_p < 0.5$) on it. The new parameters were inserted into ep1.C and the 2.56n data re-analyzed. No effect is seen in the W2 distribution sector-by-sector or in the histogram shown below

Difference between theta_p from tracking and theta_p from the electron data

W2 vs. phi_e

W2 distribution before applying the entry-109 correction to p_e

W2 vs. phi_e

W2 distribution after applying the entry-109 correction to p_e

Last shot at entry-109 electron-proton momentum corrections. I have been using the corrected (but little changed) e and p momenta in the plots of delta(qB/p) versus qB/p. I should use the uncorrected results from tracking. I fixed this and generated a new set of parameters. Upon examination of the first few I see small changes. When I look at the difference between the corrected and uncorrected curvatures I see a small (1 part in 250) shift closer to zero and no change in the width. See plot below. I give up on this stuff. I think our cooking results are so good that I am just fitting statistical fluctuations mostly in the proton tracking.

Final shot at entry-109 electron-proton momentum corrections. See text above.

Same as plot above with expanded horizontal scale.

Same as above for protons

Jerry Gilfoyle's Enotebook page 26 - R&A corrections 2 (gpg)

[Modified Wed Feb 16 00:12:12 2005 (GMT) gpg]

Testing the results from the fit. The effect of the fit on the electron momentum are close to zero. I am trying to understand that and it appears that the deviation from the calculated values is already small. The E5 data set appears to be well calibrated for the cooking. Also the spread in the data is dominated by the proton variation. The electron scatter is about 5-10 times smaller. Nevertheless, I am testing some of the results.

p_e correction slope for sector 2

Fig 1. Slope parameter for phibin=4 (sector 2).

Here is the 2D plot of $d(qB/p)$ versus $(qB/p)_{calc}$ that was used to generate the parameters in the first, non-zero bin in the above figure.

qbp_04_02

Fig 2. 2D plot used to generate parameters in Fig 1.

p_e correction intercept for sector 2

Fig 3. Intercept for this sector and phi range.

Generating ProfileX histograms in Root.

```
TProfile *px1 = qbp_04_02->ProfileX("px1",1,100,"d")
```

The plot below has cuts on coplanarity, the difference between the measured proton scattering angle and the proton angle determined from the electron kinematics, and on W. It shows the before and after corrections after I fixed the indexing error in the pcorr_ep1 class. There is essentially no improvement. The centroid shifts, but its magnitude is essentially the same as before and the width has changed much.

Fig 4. Comparision of spectra after correcting indexing error in pcorr_ep1 class.

The plot below is the same as figure 2 except I have now used the corrected electron and proton momenta instead of the ones from tracking. it appears that the correction does is shift things down.

qbp_04_02

Fig 5. Same as Figure 2 with the corrected e and p momenta instead of the tracking results.

qbp_04_02

Some hopeful results below. This figure is the first look at W_2 vs. ϕ_e after fixing the indexing error mentioned above. This is only for a single file because I'm still having problems getting the new master to work, but it does appear the sector 2 looks better and the other sectors are marginally better. The solid line is the square of the proton mass. Relative to this line sector 2 looks better and the other sectors look like they have moved from slightly below the line to above the line.

Fig 6. Before and after pictures for W2 vs. phi_e for a single run.

The plot below shows the difference between the electron momentum calculated from the measured scattering angle and the electron momentum from the track reconstruction (left panel) and the corrected electron momentum from tracking (right panel). The original, uncorrected difference is already small (6 MeV) and the distribution overlaps with zero (+/- 9 MeV). The corrected electron momentum is a little closer to zero (-3 MeV), but there is no improvement in the width of the distribution (+/- 9 MeV still). This agrees with Jeff's results based on all three running conditions, namely that the E5 data is already in good shape after cooking and this method of correcting the electron momentum has a small effect.

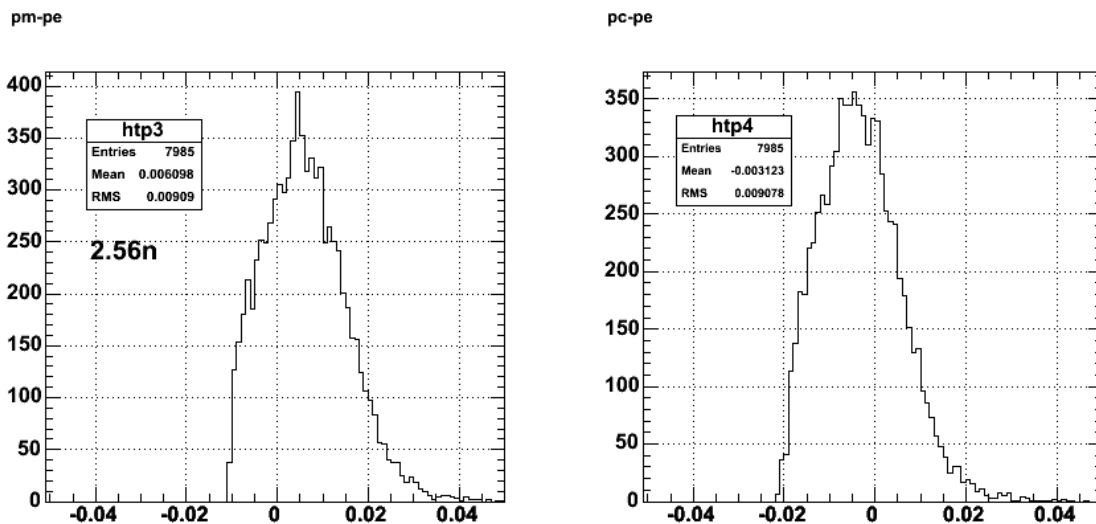

Fig 7. Comparison of the difference between the electron momentum calculated from the scattering angle measurement with the uncorrected and corrected momentum measurements.

The figure below shows the effect on W2 sector by sector of the new electron momentum corrections.

W2 vs. phi_e

W2 vs. phi_e

Fig 8. Same as figure 6 for the full, 2.56n data set.

Jerry Gilfoyle's Enotebook page 27 - R&A corrections 3 (gpg)**[Modified Thu Feb 17 21:04:47 2005 (GMT) gpg]**

Some final (maybe, sort of) results for the entry-109 electron momentum corrections. First some plots.

Jerry Gilfoyle's Enotebook page 28 - Don't use xBJ for quasi-elastic scattering (Gerard P Gilfoyle)

[Modified Thu Feb 17 22:00:40 2005 (GMT) Gerard P Gilfoyle]

I just discovered an 'interesting' kinematic property. In the past I have used Bjorken 'x' to select quasi-elastic events. BAM told me this was a bad idea because the range of W values can change. I did not understand that fully until now. The plot below reveals the problem. It shows W calculated for electron scattering off the deuteron based on the assumption of quasi-elastic scattering (i.e. I use the proton mass instead of the full deuteron mass in calculating W). The plot shows that for a cut on x of $0.95 < x < 1.05$, the range of W values that contribute increase with Q^2 .

Upper and lower limits of W values allowed by a $0.95 < x < 1.05$ cut on x.

Jerry Gilfoyle's Enotebook page 30 - ALTp at $p_m = 0.0$ (gpg)

[Modified Mon Feb 21 04:31:16 2005 (GMT) gpg]

One test of data consistency is that the asymmetry ALTp should go to zero for $p_m \rightarrow 0.0$. This is because at zero θ_{pq} (and zero p_m) you are averaging over all ϕ_{pq} and that will give zero because of the $\sin(\phi_{pq})$ dependence.

 A_{LT}' Fig 1. Plot of ALTp near $p_m = \text{zero}$.Click [here](#) to view the object (C++ code for the previous plot) you uploaded.

Jerry Gilfoyle's Enotebook page 31 - checking p_m spectra (gpg)

[Modified Fri Mar 4 05:06:47 2005 (GMT) gpg]

Using BAM's idea I generated the plots below to see if any anomalies exist in the p_m distribution. None are obvious.

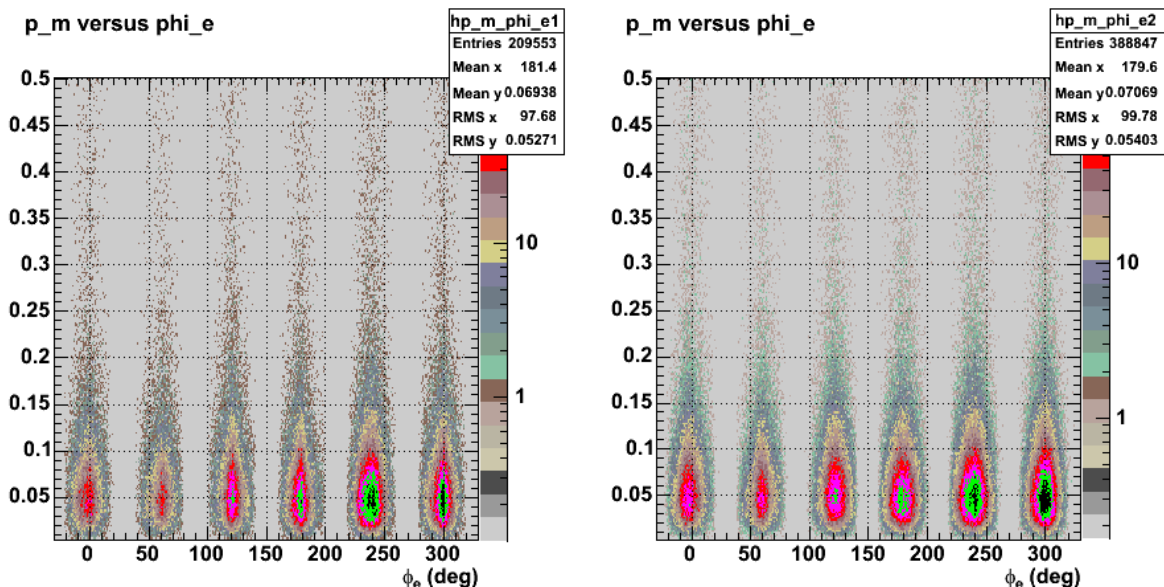

Fig 1. Plot of p_m versus ϕ_e . The left panel is with electron fiducial cuts on, the right with them off.

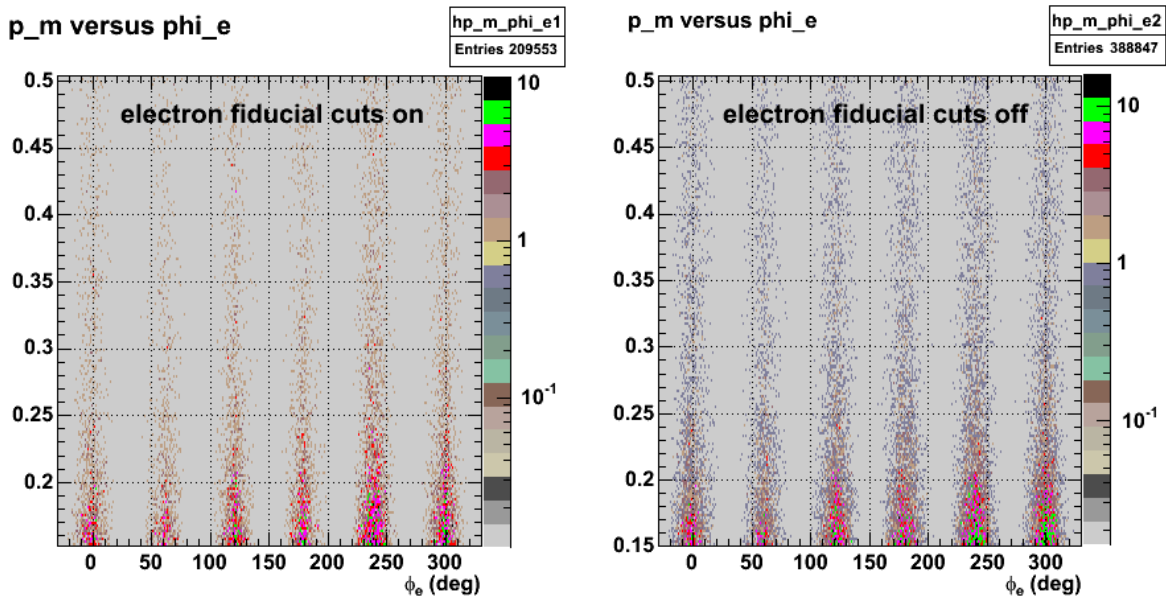

Fig 2. Same as previous plot zoomed into the region in p_m where the dip is located in ALTP.

Jerry Gilfoyle's Enotebook page 32 - theta_ vs phi_e in p_m bins (gpg)

[Modified Wed Feb 23 18:35:00 2005 (GMT) gpg]

look at before and after efid plots for theta_e vs. phi_e gated on ep(n) events in a particular p_m range. The first figure is with electron fiducials on.

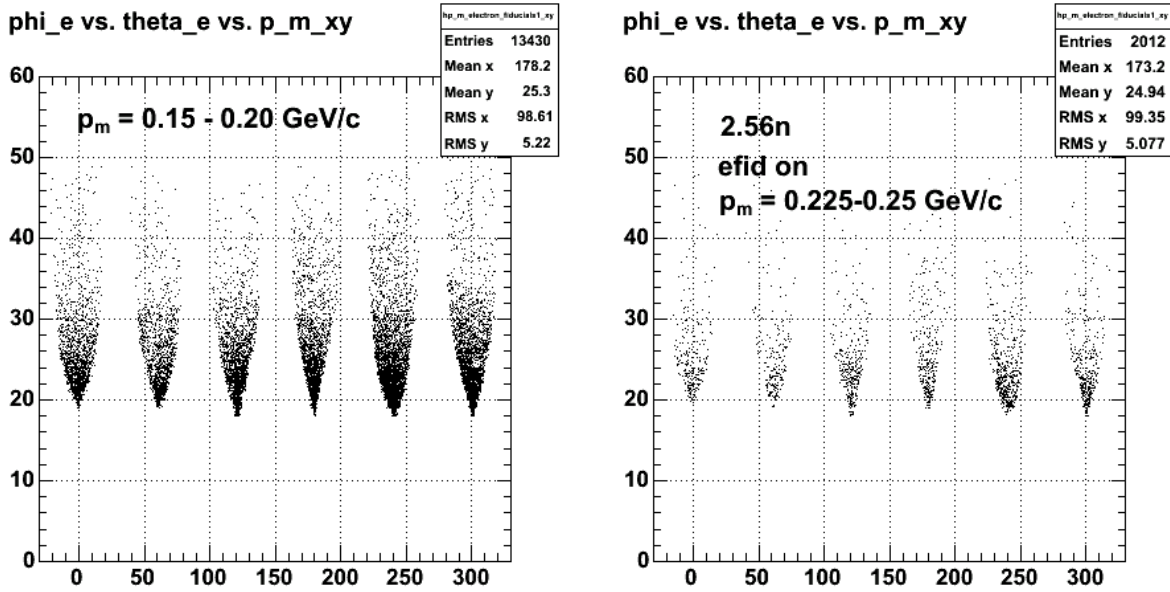

Fig 1. theta_e versus phi_e for ep(n) events from a particular p_m range.

Now turn the electron fiducials off.

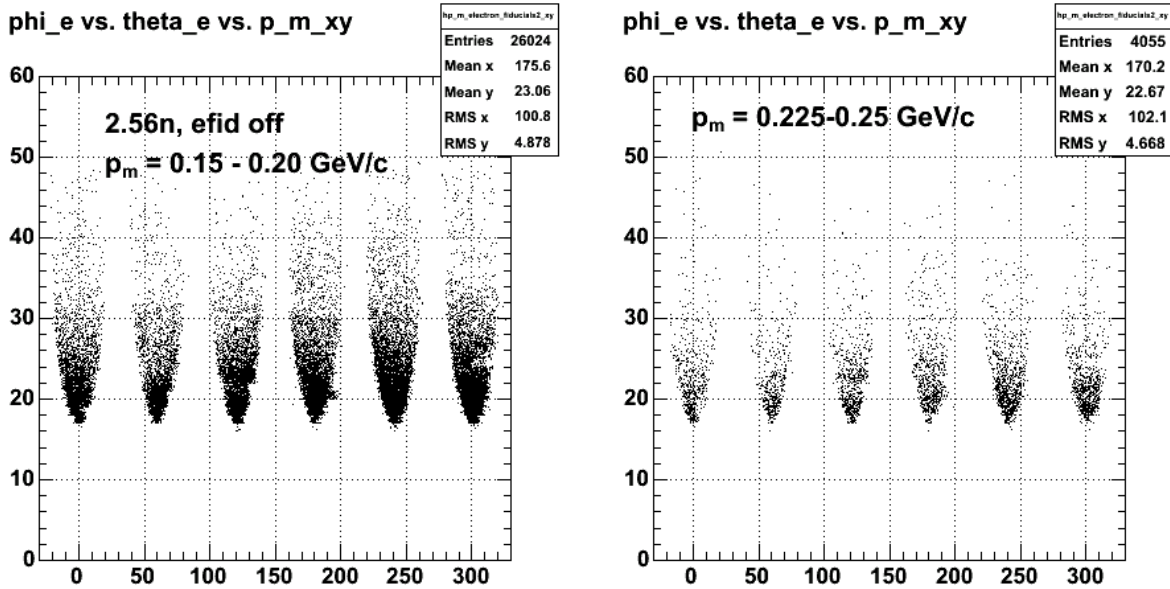

Fig 2. theta_e versus phi_e for ep(n) events from a particular p_m range.

Jerry Gilfoyle's Enotebook page 33 - Tighter efid cuts (gpg)

[Modified Wed Feb 23 22:04:48 2005 (GMT) gpg]

I modified the electron fiducial cut routine so that the cuts are now 3 degrees tighter on each side. The results are shown below. This is NUTS!

Fig 1. Added a tighter cut on the electron fiducials (green points)

Click [here](#) to view the object (Root macro for the above plot) you uploaded.

Jerry Gilfoyle's Enotebook page 34 - More tests of missing momentum (gpg)

[Modified Mon Mar 14 03:47:01 2005 (GMT) gpg]

The plots below show the 2D spectra of missing momentum p_m versus ϕ_e . The spectra on the right had no electron fiducial cuts, but did have all the other usual suspects turned on. The spectra on the left is for events that are OUTSIDE the electron fiducial cuts. These are the events on the rim of each sector.

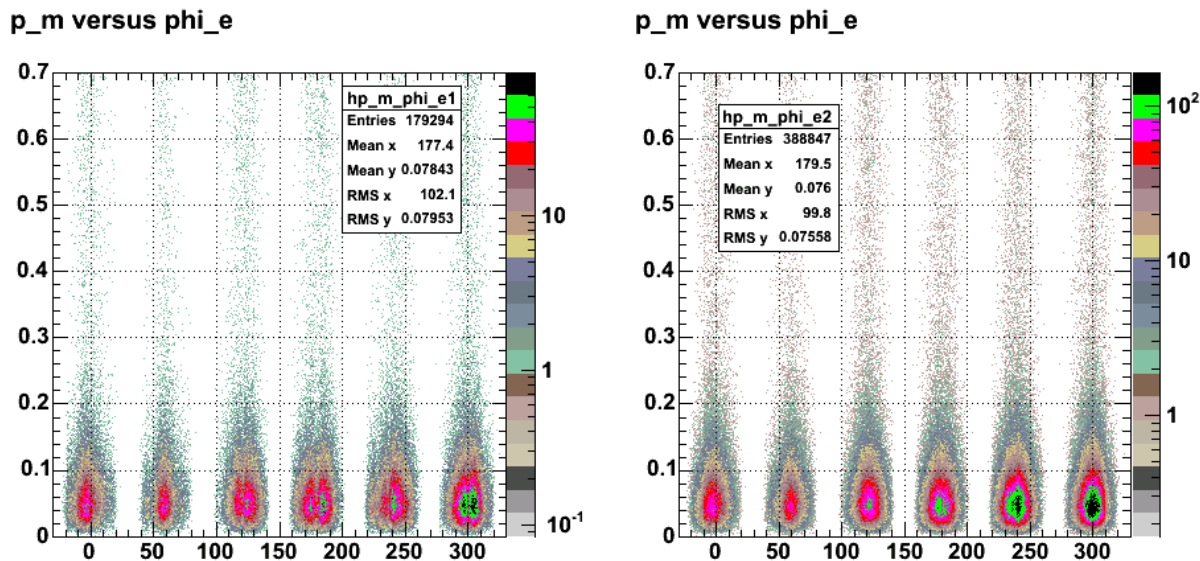

Fig 1. Comparison of p_m versus ϕ_e for events outside the electron fiducial cuts (left panel) and ones with no electron fiducial cuts turned on.

Below is a plot of all three p_m spectra.

The plot below is the summary for sector 1 of the comparison between the p_m spectrum for events in the electron fiducial region and those outside as suggested by BAM. The normalized difference spectrum is defined as the bin-by-bin difference between the p_m histogram of the events in the electron fiducial region and those outside it corrected for different yields. In other words

$$N_{\text{diff}} = N_{\text{out}} - C \cdot N_{\text{in}}$$

where C is the ratio of the total yield outside the fiducial region to the yield inside the fiducial region. The red and green spectra in the top panels are both very similar to the black histogram for the p_m distribution with no electron fiducial cuts turned on. This similarity is also shown in the lower left panel. This is the normalized difference. There is a small (difference 50 events out of 600) at small p_m (about 50 MeV/c) which is 2-3 sigma outside the statistical variation. The burning question has been whether there was any evidence of a distortion in the reconstruction of events falling outside the the electron fiducial cuts that would account for the enhanced amplitude in ALTP at large p_m when the electron fiducial cuts are turned on. The normalized difference spectrum in the lower left panel is zero at large p_m meaning there is little or no difference in the two spectra. This would mean that BAM's concern about a mistake in the reconstruction for events near the coils does not appear to be true. This is almost bad news since it would have provided an explanation for the enhanced ALTP amplitudes at large p_m . However, the effect may be due to KJ's explanation or, even more simply, due to a different Q^2 distribution when the electron fiducial cuts are turned on. Also I have to check ALL the sectors before I can definitively draw that conclusion.

Jerry Gilfoyle's Enotebook page 35 - Electron Fiducial Dependence of ALTp (GPG)

[Modified Thu Mar 17 21:47:35 2005 (GMT) GPG]

We have discovered recently that the use of tight electron fiducial constraints can have a significant effect of the fifth structure function asymmetry (ALTp). The electron fiducial cuts were described earlier [1](#), [2](#), [3](#), and [4](#). The effect of turning these fiducial cuts on and off is shown in Figures 1-2. Figure 1 shows the effect of the fiducial cuts on the CLAS acceptance. The results are pretty typical.

Fig 1. Effect on electron fiducial cuts on the CLAS electron acceptance.

The second figure shows the effect on ALTp of turning the electron fiducial cuts on and off. When the amplitude of the asymmetry is small there is little of no effect. When the asymmetry becomes significant, then the effect becomes large. It is a full factor of three for the point at $p_m = 0.24$ MeV/c and a factor of about 2.5 for $p_m = 0.65$ MeV/c.

Fig 2. Effect of electron fiducial cuts on the fifth-structure-function asymmetry (ALTp).

Bernhard raised the concern that there might be a problem reconstructing tracks near the coils and along the edges of the CLAS acceptance. There are the events excluded by the new tighter electron fiducial cuts. His concern is that a small mistake at low p_m could push events out to larger p_m . Since the cross section is dropping rapidly with p_m , a small mistake at small p_m could have a large effect at higher missing momentum. To test this idea consider Figures 3-4. Figure 3 shows the p_m distribution sector by sector under three sets of cuts. The black histogram in each panel has no electron fiducial cuts. The blue histogram has the electron fiducial cuts turned on. Everything else is the same as the black histogram. The red histogram represents the p_m distribution for events EXCLUDED by the new electron fiducial cuts. These are the events we throw out.

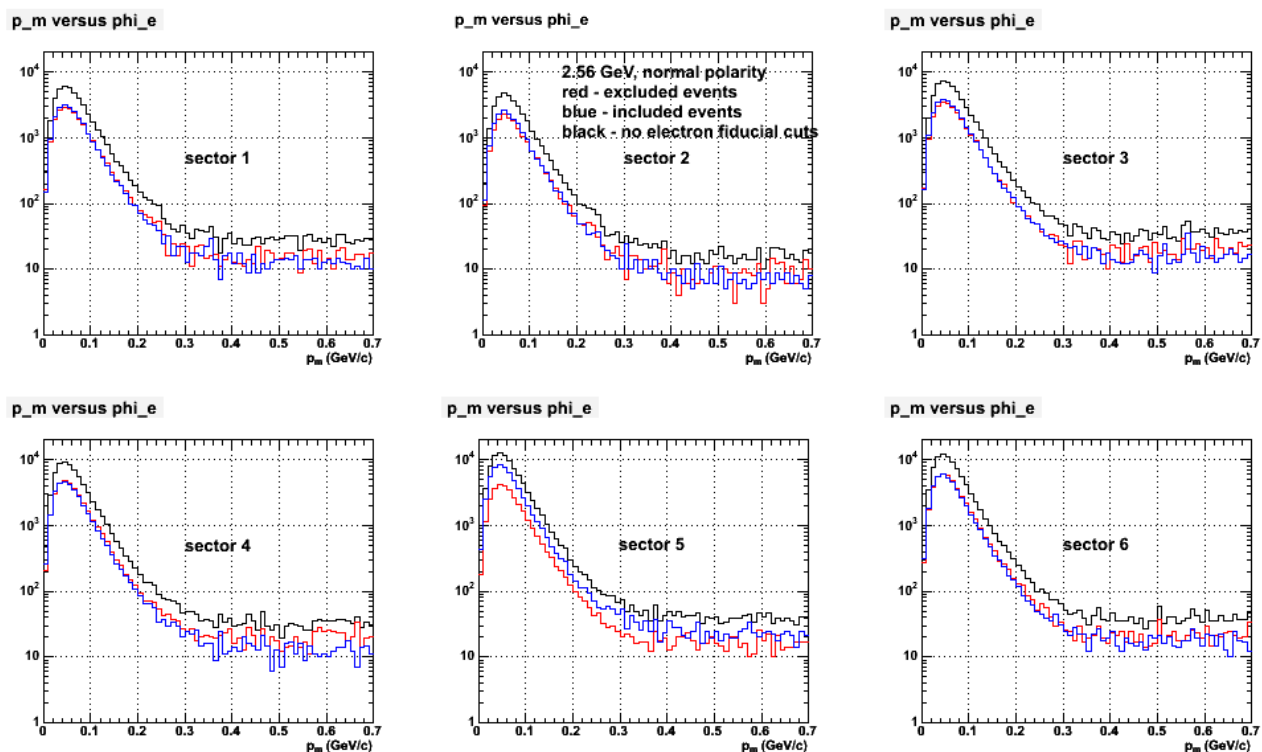

Fig 3. Missing Momentum distribution sector by sector for events with no electron fiducial cuts (black), with the electron fiducial cuts on (blue), and events excluded by the fiducial cuts (red).

In each sector all three curves have much the same shape. They differ on in overall scale. It is intriguing to me how close the red and blue curves are to one another. The excluded events look exactly like the included ones. It would appear there is no significant difference between the included and excluded events and the reconstruction is not a problem for these events.

To test this idea a bit further we generated the spectra shown in Figure 4. A comparison is made between the missing momentum spectrum for events in the electron fiducial region and those outside as suggested by BAM. The normalized difference spectrum is defined as the bin-by-bin difference between the p_m histogram of the events in the electron fiducial region and those outside it corrected for different yields. In other words

$$N_{diff} = N_{out} - C * N_{in}$$

where C is the ratio of the total yield outside the fiducial region to the yield inside the fiducial region. In each sector there is a small (difference 50 events out of 600) at small p_m (about 50 MeV/c) which is 2-3 sigma outside the statistical variation. The burning question has been whether there was any evidence of a distortion in the reconstruction of events falling outside the the electron fiducial cuts that would account for the enhanced amplitude in ALTP at large p_m when the electron fiducial cuts are turned on. The normalized difference spectrum for each sector is zero at large p_m meaning there is little or no difference in the two spectra. This would mean that BAM's concern about a mistake in the reconstruction for events near the coils does not appear to be true. This is almost bad news since it would have provided an explanation for the enhanced ALTP amplitudes at large p_m . However, the effect may be due to KJ's explanation or, even more simply, due to a different Q2 distribution when the electron fiducial cuts are turned on.

Fig 4. Comparison of missing momentum distribution sector by sector using the normalized difference defined in the text.

The normalization factors used for each sector are listed below.

Jerry Gilfoyle's Enotebook page 37 - more comparisons of ALTp to study electron fiducials effect (gpg)

[Modified Tue Jan 10 19:55:34 2006 (GMT) gpg]

We noticed soem weeks ago this surprising dependence of the fifth-structure function asymmetry ALTp on the use of our new, tighter electron fiducial cuts. One explanation offered by Kyungseon Joo at the last collaboration meeting is that we have to be careful when extracting ALTp in regions where the CLAS acceptance is changing rapidly. In such a case the ratio method may not be as effective in cancelling out acceptance effects. My interpretation of KJ's argument is here. One place where this effect might be seen is in the Q2 behavior. The cross section rises rapidly as Q2 decreases until we start losing events down the beam line and the CLAS acceptance goes to zero. To investigate this idea I have generated the following plots. The plot below is the original plot showing the effect of turning on the electron fiducial cuts. Events of all Q2 are accepted here.

Fig 1. Plot of the fifth-structure-function asymmetry ALTp showing the effect of turning the electron fiducial cuts on. The full Q2 range4 is included.

Now put a cut on the 4-momentum transfer so $Q^2 > 0.7 \text{ (GeV/c)}^2$. This restricts the data to the region above where the CLAS acceptance is starting to seriously cut into the Q2 distribution. The position of the cut is shown in Figure 2. The effect on ALTp is shown in Figure 3. Notice the effect of the electron fiducial cuts is smaller for $p_m < 0.45 \text{ GeV/c}$ and the previous difference at $p_m = 0.24 \text{ GeV/c}$ has gone away.

Fig 2. Q² distribution with cut shown.

Fig 3. ALTp with electron fiducial cuts on and cut on Q2.

2005-04-01 10:32:88

Fig 4a. Modified version of Figure 4 with restricted horizontal range to make it consistent with Figure 1.

Fig 5. Q2 distribution with efid off

Click [here](#) to view the object (Root macro for above plot of Q2) you uploaded.

To study this a bit further, we generated the plot below (see Fig 6) to compare the Q2 distribution for the electron singles events with the electron fiducial cuts turned on and off. Not surprisingly the fiducial cuts throw out events mostly at low Q2 and few events at high Q2. The original effect of the fiducial cuts may simply be caused by the difference in the Q2 distribution of the events used to extract ALTp. The $Q^2 > 0.7 \text{ (GeV/c)}^2$ cut used above would reduce this difference because the electron fiducial cuts have a small effect at higher Q2 as shown in the plot below. Of course, there is the sudden appearance of the anomalous peak at low Q2 for events with the electron fiducial cuts turned on. For a discussion and analysis skip over the next paragraph and figure and go to Fig 7.

A later (Jan, 2006) follow-up check found that a large portion of the problem is due to a mistake in the neutron selection. The cut on MM2 used above to select neutrons was 0.90-0.98 GeV2. This would have been roughly correct for MM, but not for MM2! With the proper MM2 cut on, the difference in ALTp with fiducials on and off almost goes completely away. See entry [109](#), Fig 1. I then took that analysis and changed the MM2 range to the mistaken one (MM2=0.90-0.98) and got the following result for ALTp (Fig 5.1). It exhibits some of the same problem as we saw earlier. There is not complete agreement with the previous version of ALTp, but I am also using a different QE cut ($W_n=0.92-1.0$) in the recent (1/06) analysis. The choice of this cut for W_n was determined in the analysis used for the Feb, 2005 NPWG talk. See entry [250](#) in the E5 elog.

Fig 5.1 Comparison of AL_T' with (red) and without (blue) electron and proton fiducial cuts on and with the old (wrong!) cut on MM² to select neutrons.

Of course, there is the sudden appearance in Fig 6 of the anomalous peak at low Q² for events with the electron fiducial cuts turned on. The next figure (Fig 7) shows phi_e versus Q² for events with the electron fiducial cuts on. Notice the large clump of events at low Q² associated with sectors 1 and 2. These events disappear when the quasi-elastic cut is turned on so it may not be important for our analysis, but they are still a mystery.

Fig 6. Comparison of Q² distribution with electron fiducials off (black) and on (red). Note the odd peak at low Q².

KJ's explanation

① We have assumed

$$A'_{LT} = \frac{\sigma^+ - \sigma^-}{\sigma^+ + \sigma^-} = \frac{A^+}{A^-}$$

What \uparrow
we want

so $A^+ = A^-$ and can

② What we really want

$$\int_{a^+}^{a^-} \sigma^+(x) A^+(x) dx - \int_b^c$$

KJ explanation

KJ's explanation

① We have assumed

$$A'_{LT} = \frac{\sigma^+ - \sigma^-}{\sigma^+ + \sigma^-} = \frac{N^+ - N^-}{N^+ + N^-} = \frac{\sigma^+ A^+ - \sigma^- A^-}{\sigma^+ A^+ + \sigma^- A^-}$$

↑ What we want ↑ What we measure

so $A^+ = A^-$ and cancels in the ratio.

② What we really measure is

$$\frac{\int_{bin} \sigma^+(x) A(x) dx - \int_{bin} \sigma^-(x) A(x) dx}{\int_{bin} \sigma^+(x) A(x) dx + \int_{bin} \sigma^-(x) A(x) dx}$$

$x =$ some kinematic variable
(p_m, E_{pg}, Q^2, \dots)

so the acceptance does not simply cancel

③ an extreme example

④ Possible solution.

Measure A' when the entire acceptance is flat.

Jerry Gilfoyle's Enotebook page 38 - codes for determining electron fiducials (gpg)

[Modified Mon Mar 28 16:48:40 2005 (GMT) gpg]

Below are a series of links to codes for generating the electron fiducial cuts I am using for the E5, ALTP analysis. Each code is heavily commented with guidance on how to run it. If you have any questions, let me know. I may or may not be able to answer them. No guarantees on the accuracy or precision of these codes.

Jerry Gilfoyle's Enotebook page 39 - More tests on ALTp (gpg)

[Modified Fri Apr 8 16:25:31 2005 (GMT) gpg]

The plot below is a further comparison of ALTp extracted versus missing momentum p_m . The new development below is to look at the effect of cutting down the size of the azimuthal acceptance by ± 3 deg to see what effect it has on ALTp. The cut of the Q2 to get rid of the Q2 region where the CLAS acceptance is rapidly falling (the beam pipe) is also included.

Fig 1. ALTp versus p_m with an additional reduction of the azimuthal acceptance for each θ_e bin of ± 3 deg.

Click [here](#) to view the object (Root macro to make the above plot) you uploaded.

The plot above is flawed. The green points are very close to the blue ones. The green ones are ones where I restricted the azimuthal range of the electron fiducial cuts by an additional 3 degrees. I discovered after running the code that the electron fiducial cuts were turned off so the additional ± 3 deg cut should have no effect. The difference between the green and blue points is probably due to slightly different files since the number of nodes and thus data files) changed recently.

The plot below is what Figure 1 should have been. I reduced the azimuthal range of the electrons an additional 3 degrees on each side of the range to see the effect on the asymmetry. For most points the change was as anticipated; the uncertainties increase because the statistics are worse, and there are small, statistically insignificant changes in the value of ALTp. The two exceptions are the points at the smallest missing momentum p_m and at $p_m = 0.28$ GeV/c. The excursion at $p_m = 0.05$ GeV/c is the most troubling since it should be approaching zero and the statistics are pretty good here.

2005-04-08 10:32:28

Fig 2. Revised version of Fig 1. See text.

Click [here](#) to view the object (Root file for above plot) you uploaded.

The plot below shows a fit to the helicity asymmetry in that first p_m bin. The uncertainty is considerably larger here. This may be the issue about calculating the method for calculating the uncertainties. For the fit shown below, the asymmetry is less than two standard deviations away from zero so this may just be a problem with understanding the uncertainties.

2005-04-08 10:50:08

Jerry Gilfoyle's Enotebook page 40 - The low Q2 anomaly (gpg)

[Modified Fri May 13 04:11:57 2005 (GMT) gpg]

This entry is motivated by the observation of some mysterious low-Q2 peaks in the Q2 spectrum in sectors 1-2. These events are first reported in entry [37](#). These peaks (see Figure 2) turned out to be events that should have been excluded by the fiducial cuts, but passed them because of singularities and some unforeseen behavior of the functions used to determine the fiducial cuts when the events came well inside the normal region of the fiducial cut curves. The details are below.

event by event analysis

phi_e vs. theta_e vs. p_e_xy

Fig 4. The low-Q2 anomaly is restricted to bnads on phi_e.

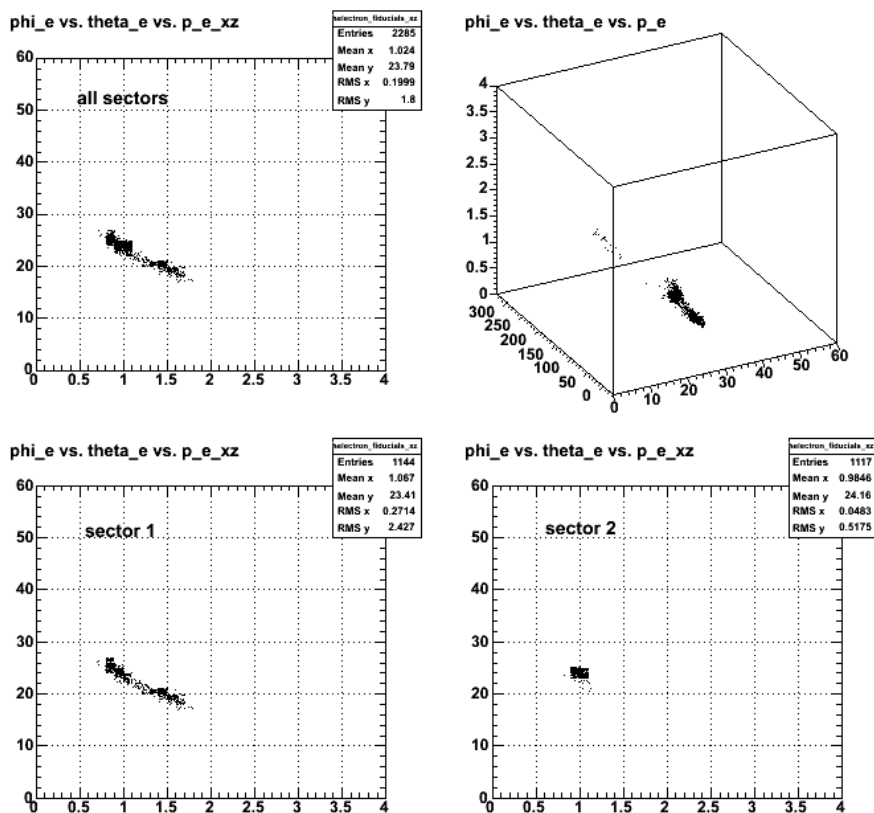

Fig 5. theta_e vs. momentum dependence for low-Q2 events.

This is still a mystery to me. The problem is probably with the measurement of the electron energy and/or momentum. We get the polar angle for the track in region 1 (mostly) so we know that reasonably well. The low-Q2 events show up even with electron singles so it's a problem with the scattered electron energy. I'm not sure what the signature would be for a screwed up electron measurement.

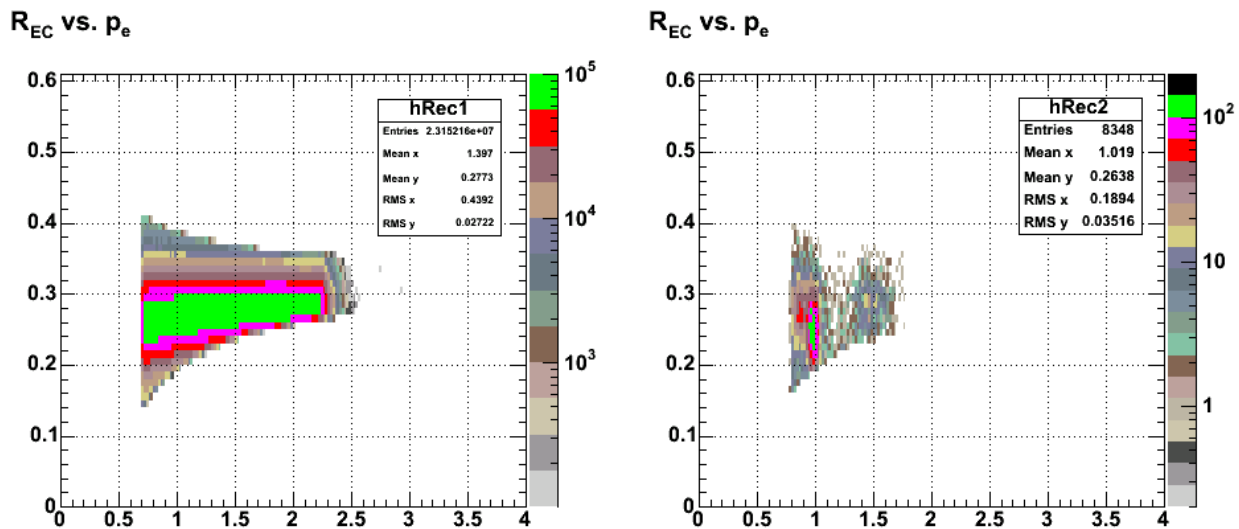

Fig 6. This shows the ration Rec of the total energy of the electron from the EC (calorimeter) to the electron energy extracted from the track (DC information) as a function of the momentum from the tracking. The left panel is all the electrons, the right panel is for events with Q2 < 0.5 GeV2.

Fig 8. Comparison of anomalous events for ep coincidences (left panel) and electron signles (right panel).

phi_e vs. theta_e vs. p_e_xy

phi_e vs. theta_e vs. p_e_xy

Fig 9. Comparison of anomalous events for ep coincidences (left panel) and electron singles (right panel).

The plot below is a look up the beam line at the EC hit position of the low-Q2 events (black) and the electron singles events. What is striking and disturbing is that the low-Q2 events appear to be coming outside the EC fiducial region. These data have the EC fiducial cut on them so these events should never make it through.

phi_e vs. theta_e vs. p_m

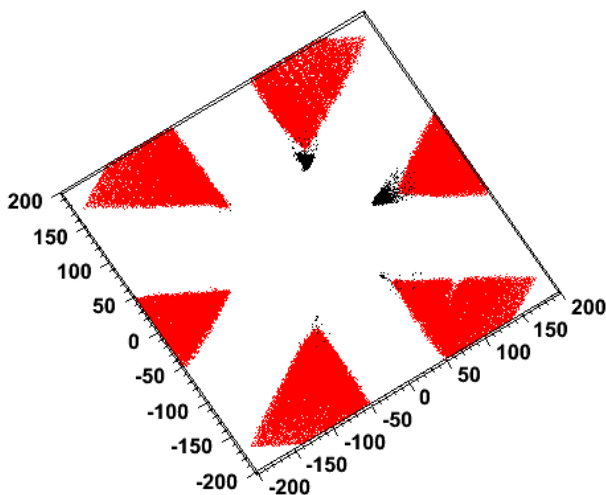

Figure 10. The EC hit position of the low-Q2 events (black) and the electron singles events (red).

The plot below shows the x-y positions of the EC hits with the electron fiducials on and off. The low-Q2 events are passing the EC fiducial cut, but they should be getting cut out by the electron fiducial cuts. They're NOT! This is like the problem that Nikolai has seen, but much less frequently. The results in Figure 11 are for a single run for electron singles. The results above in Figure 10 are for the full 2.6n data set.

Fig 11. EC hit positions with electron fiducial cuts off and on.

I'm beginning to see the problem. The figure below shows the fiducial curves used for one of the low-Q2 anomalies. Notice the singularity in the curve near $\theta_e=20$ deg. This is an intrinsic feature of the function I am using. The anomalous point is one that passes the EC fiducial cut and should be excluded by the fiducial cut, but it is not. The θ_e angle is below the singularity of the function where the curve has changed sign so this event now passes the cut (see the point indicated in the figure by the arrow).

Fig 12. Fiducial curves for low-Q2 anomalous event. There are vertical lines for both red and blue curves at the singularity at near $\theta_e=20$ deg. The blue curve is the only one visible in this region because it sits atop the red curve.

Modifying the eod5.C code to get rid of these events yields the results shown below. Compare with Figures 10 and 11 above.

phi_e vs. theta_e vs. p_m

Fig 13. Plot of the hit positions of the electrons on the calorimeter.

Final resolution of the low-Q2 anomaly. The plot below shows the x-y hit positions for electron tracks on the calorimeter with the electron fiducial cuts on (red) and off (black). The EC fiducial cuts are on in both cases. If you compare this plot with Figure 11 you see the anomalous peaks at the small-angle apex of the EC in Figure 11 have disappeared. These were the events making up the low-Q2 stuff in Figure 2-5 which got through the cuts as described above in the discussion of Figure 12. Yippeee!!!!

Fig 14. Comparison of EC hit positions with electron fiducial cuts on (red) and off (black). The EC fiducial cuts are on in both cases. Compare with Figure 11.

Fig 15. Final plot showing Q2 distribution for 2.6 , polarity data. Note the lack of the mysterious low-Q2 peak seen in Figure 2.

I started worrying about Fig 4 above which shows that when the broken electron fiducial is turned on, you get the odd-looking distribution of events in θ_e versus ϕ_e . I was concerned because I thought the events with the electron fiducial on that still get through the fiducial cut extend out to almost 30 deg. I thought these events should get cut out by the correctly-working part of the electron fiducial cut. This is not the case as shown in the figure below. The left panel shows the acceptance in θ_e versus ϕ_e when $Q^2 < 0.5$ GeV², the EC fiducial cut is on, and the 'broken' electron fiducial cut is on. You see this odd distribution of events. When you turn the electron fiducial off completely you get the distribution in the right-hand panel. These are now events cut only by the EC fiducial cut and they extend out to 30 deg.

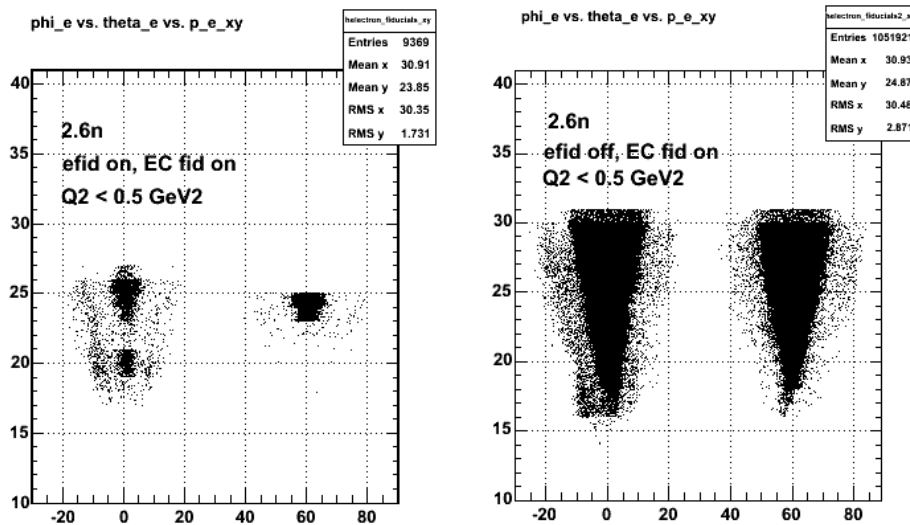

Fig 16. Acceptance plot (θ_e vs. ϕ_e for electrons with $Q^2 < 0.5$ GeV² with EC fiducial cut on (both panels), incorrect electron fiducial on (left panel), and electron fiducial off (right panel).

Jerry Gilfoyle's Enotebook page 41 - running exclurad for JL (gpg)

[Modified Fri Jun 10 14:55:38 2005 (GMT) gpg]

To do the E5 radiative correction start in /home/gilfoyle/eod/exclurad/run/lachniet on pscm1 and run

```
make_exclurad_script2.pl beam_energy qsq

Jerry Gilfoyle's Enotebook page 42 - First proton fiducial look (gpg)

[Modified Mon May 9 19:34:56 2005 (GMT) gpg]

Below is my first look at the proton fiducials in coincidence with an electron. We excluded quasielastic, ep events because they are strongly correlated with the electron and don't produce flat, trapezoidal distributions in ϕ_p . The first curious thing is the large angle proton peak. Does this make sense??

The analysis in the files below was done excluding quasielastic events in the range $0.92 < W < 1.0$ which is a fairly tight constraint on the QE events. Consequently there may be (and there does appear to be) a considerable amount of quasielastic strength in the results shown below.

Click [here](#) to view the object (Root file containing data used for plots below) you uploaded.

Looking at the plots of the edges positions (Fig 7) and comparing them with the CLAS acceptance (Fig 8-10) I am afraid that if I use the edges from these gen1 fits I will be cutting out a large fraction of the QE peak. the problem is shown in Fig 12 which shows the simple trapezoid fit to the phi_p distribution for the p_p = 0.7 GeV and theta_p = 60 deg bin. Notice the central peak in the data is wider than the plateau of the fit. It seems like there is a set of events that are near-QE-like that form a peak in the middle of the distribution and sit atop the stable acceptance region (recall the acceptance plots above).

Fig 12. Phi_p distribution for pbin=7, thetabin=60 plus simple trapezoid fit.

Just be looking at the acceptance plots, the central plateau is about 15 deg wide or great in each momentum pin. Go into trapzoid.fit and set a minimum for this parameter in Minuit. The results are below.

Click [here](#) to view the object (Fig 13. Plot of edges for $0.76 < W < 1.16$ GeV and with a minimum plateau width of 15 degrees for $\theta_p > 25$ deg) you uploaded.

Big mystery!! Why is every other point missing in Fig 12??? Because I didn't include the chi2 in the read statement. The chi2 plots are shown below. The chisquare appears to get noticeably worse when the threshold requirement really starts to have an effect, but I'm willing to live with this in order to capture the QE events within the proton fiducial cuts.

Jerry Gilfoyle's Enotebook page 45 - Excluding more quasielastic events (gpg)

[Modified Fri May 20 18:19:23 2005 (GMT) gpg]

The plots below show the results of raising the minimum W required so that we exclude quasielastic events because they electrona and proton in those events tend to be correlated and ruin the nice flat acceptance of CLAS.

Fig 1. Acceptance for events with $W > 1.65$ GeV and all fiducials off.

Click [here](#) to view the object (Root histogram file for above plot in Fig. 1) you uploaded.

Now crank the W threshold up to 1.9 GeV and get the following.

Fig 7. Coplanarity angle for 2.56 GeV, normal polarity run.

Figure 7 is perplexing because one expects that the cross section or number of events at 360 degrees should be the same as the number of events at zero degrees. However, this is not true in this case because the coplanarity is based on the difference between two angles. The difference $\phi_e - \phi_p$ is close to zero whenever the electron and proton come out close to the same direction and lying in the same quadrant. This can occur for almost all possible values of ϕ_e and ϕ_p . To get a difference $\phi_e - \phi_p$ close to 360, this only happens only when the electron angle is close to, but does not exceed 360 degrees and the proton is close to zero degrees, but does not go below 0 degrees (and hence change to some value close to 360). This second situation is only true for a very small region of the detector around the x axis in the lab coordinate system.

Fig 8. CLAS proton acceptance for ep coincidence that exclude events that are coplanar because they will tend to be quasielastics.

Click [here](#) to view the object (Root file for Fig 8) you uploaded.

In last week's meeting (5/13/5) there were several questions that were raised about the proton acceptance. (1) What is the source of the large number of events in the range $70 < \theta_p < 140$ degrees (see Figure 1). The most likely answer appears to be these events are from pions ($ed \rightarrow e\pi + X$) that get misidentified as protons. Pions can reach large angles like this while protons can't. (2) The second question was about the shape of the large proton group in the region $50 < \theta_p < 70$. The acceptance for electron singles typically tails off at large θ_e so that the acceptance away from the CLAS coils is uniform for a given θ_e bin. The proton acceptance shown in Figure 1 is not flat, but rounded in the region $50 < \theta_p < 70$. One possible explanation for this shape is that it represents the electron acceptance at forward angles. These are ep coincidences and protons at $\theta_p = 50-70$ degrees likely come from electrons produced at forward angles where the electron acceptance has a shape like this (except it's inverted) which in turn effects the proton acceptance. (3) There appear to be a significant number of quasielastic (QE) events in this sample. The electrons and protons in QE events are correlated which distorts the flat acceptance of CLAS. The question is how do we get rid of these events so the acceptance away from the coils is flat as a function of ϕ_p in a given θ_p bin. We tried several things. First, we turned off the electron and EC fiducial cuts. This significantly increased the number of events in the sample as expected, but did not significantly change the shape of the proton acceptance in the range $\theta_p = 50-70$ degrees. We then tried excluding more and more of the events near the quasielastic peak by applying a threshold on W . This reduced the number of quasielastic events, but did not eliminate them (see Figure 1 in this entry). There is still enough of a correlated QE peak at large θ_p to distort the fits using a simple trapezoidal shape. The next step we took was to apply a coplanarity cut. We expect quasielastic events to be correlated and to lay in the same plane. We eliminated events by calculating the difference between the electron and proton

azimuthal angles and excluding events near 180 degrees so $177 < |\phi_e - \phi_p| < 183$ degrees. Some of the results are shown below.

Fig 9. Tune the W range to increase the sample size. This looks like the W threshold is too low because the proton acceptance is not flat in the range $\theta_p = 50-70$ degrees.

Jerry Gilfoyle's Enotebook page 46 - Including positive pions with the ep events (gpg)

[Modified Thu Jun 9 21:23:40 2005 (GMT) gpg]

At WKB's suggestion, I included $e+d \rightarrow e+pi+$ events with the $e+d \rightarrow e+p$ I was already using to get the hadron fiducial cuts. This inclusion is based on the assumption/standard wisdom that the proton and positive pion fiducials should be the same. The plot is below in Figure 1. The ϕ_h dependence in each sector now appears very smooth except in the range $\theta_h = 50-70$ degrees where we see the same reflection of the forward-angle electron acceptance that we saw in the previous two entries.

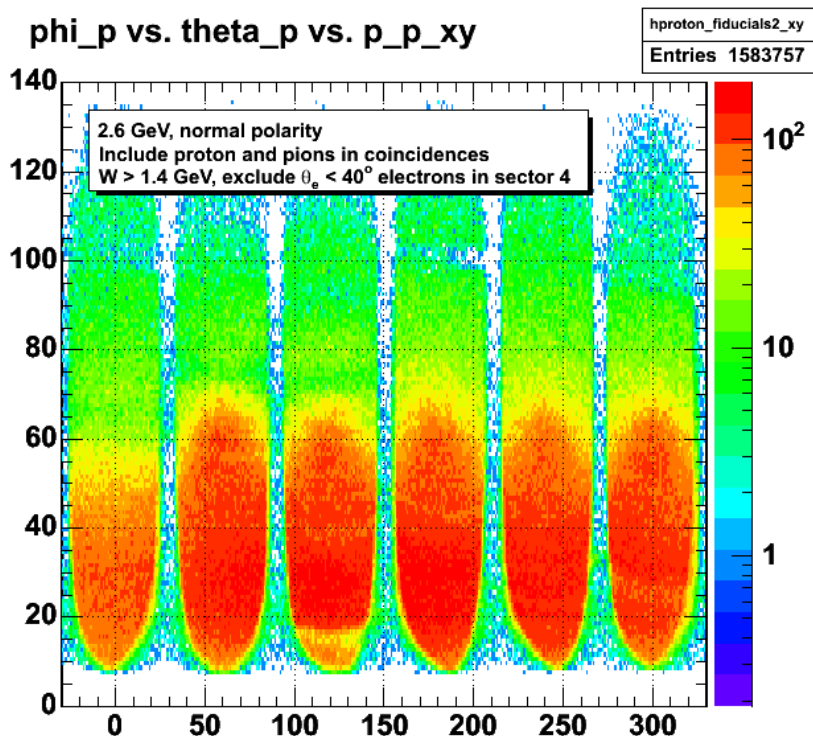

Fig 1. Hadron acceptance for $W > 1.4$ GeV, no electron fiducials.

Click [here](#) to view the object (Root file for Fig 1) you uploaded.

The rounded shape of the proton acceptance in the range $\theta_p=50-70$ degrees has been attributed to the effects of the electron acceptance at the most forward angles. To test this idea we decided to put a cut on those forward-angle electrons in one sector only. We put the cut on electrons in sector 4 which should effect the protons in sector 1 since a large proportion of the electron-proton coincidences lie in the same plane. This cut should have little effect on the pions. The results are shown below and support the idea that the shape of the proton acceptance around $\theta_p = 60$ degrees is due to the electron acceptance of CLAS at the most forward angles.

2005-05-22 08:03:21

Fig 2. Try excluding electrons in sector 4, $\theta_e < 40^\circ$ to see if it effects the rounded shape of the proton acceptance in the range $\theta_p = 50-70$ degrees in sector 1. These results are for about one-fourth to one-third of the data.

The next step in the analysis would be to cut on the electrons in all the sectors to get rid of the proton peninsula and then we will have a smooth, flat distribution in each sector out to large hadron angles. The first attempt at this is shown below. The proton acceptance is flatter, but still not as flat as we would like. Fig 3 shows the proton acceptance with a $\theta_e > 30^\circ$ cut on it. Raise this threshold to 40 deg.

2005-05-22 09:09:05

Fig 3. Try excluding electrons in all sectors, $\theta_e < 30^\circ$ to see if it effects the rounded shape of the proton acceptance in the range $\theta_p = 50-70$ degrees. These results are for the full dataset.

The results of raising the threshold on the electron scattering angles is shown below. The phi distribution in each sector is now pretty flat so we'll save this data set for the first generation fits (Opps! Maybe not. See below. It also appears that we will have to put an upper limit on theta_p (about 90-100 deg) where we run out of events.

2005-05-22 10:20:88

Fig 4. Try excluding electrons in all sectors, $\theta_e < 40$ deg to see if it effects the rounded shape of the proton acceptance in the range $\theta_p = 50-70$ degrees. These results are for the full dataset.

Click [here](#) to view the object (Root file for Fig 4) you uploaded.

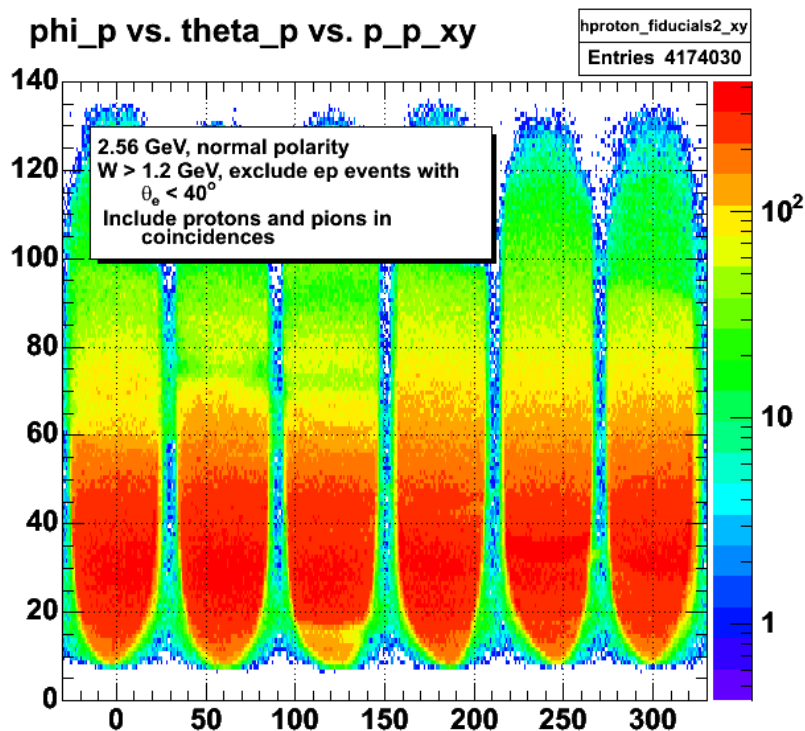

The number of events in Fig 4 has dropped dramatically from Fig 3 (a factor 4) so let's play around to see if we can recover some of those events. As a first attempt change the W requirement from $W > 1.4$ GeV to $1.2 < W < 1.75$ GeV.

2005-05-22 11:31:43

Fig 5. Try limiting the W range to $1.2 < W < 1.75$ GeV to see if I can get more counts. Doesn't seem to work.

Now use $W > 1.2$ GeV threshold and exclude only ep coincidences with $\theta_e < 40$ deg (i.e., include the epi+ coincidences). The hope here is that we recover a significant fraction of events and the plot below shows that appears to be true.

2005-05-23 04:43:28

Fig 6. Use $W > 1.2$ GeV threshold and exclude only ep coincidences with $\theta_e < 40$ deg.

Click [here](#) to view the object (Root histogram file for Fig 6) you uploaded.

Doing the gen1 fits reveals there is still a significant QE peak in the data even in the range $\theta_p = 55-65$ deg. See the PS file below. This is surprising since there is not a hint of it in Fig 6.

[Fig 7](#). Proton acceptance for ep/epi+ events from the previous analysis.

Oops! Pilot Error! The plots in Fig 7 and the gen1 fits were generated for the wrong histogram so redo the gen1 fits. The correct acceptance plot is shown below.

The plot below shows a comparison of the edges found in the first generation fitting using the trapezoid fit for two different data samples. The red points are from the mixed sample discussed in this entry consisting of protons and positive pions. The black points are the first generation fits for one of the previous protons-only samples. These results are for pbin=10 and sector 1, 2.6 GeV, normal polarity. For theta_h angles less than about 50 degrees the first generation fits are consistent. At larger angles the edges found with the proton sample follow the contours of the quasielastic peak and create a 'wineglass' effect that, while pretty, does a lousy job of reproducing what we think is the true region of uniform acceptance.

Comparison of proton and proton- π^+ samples

Fig 12. Comparison of edges found in the proton-only sample and in the sample consisting of protons and positive pions.

Important question!!!! What are the maximum and minimum energies for quasielastic protons for this energy? The proton momenta vary with Q^2 as shown in the table below.

Check on $p_{bin}=14$ where the fit parameters for the upper portion of the sector are anomalously high. The plot below shows a comparison of the upper distribution for $p_{bin}=14$ along with the distributions in the adjacent momentum bins. The distributions don't show any great differences except for 1-2 points. I could putz around and tune things, but I think that would have the same effect as just punting the $p_{bin}=14$ point.

Jerry Gilfoyle's Enotebook page 48 - 3rd look at proton/hadron fiducials (gpg)

[Modified Thu Jun 2 23:18:58 2005 (GMT) gpg]

At Will and Brian Quinn's suggestion, I have generated the acceptance for all positively charged tracks associated with a good electron track and with $W > 1.2$ GeV. I have excluded events where there is a proton in the sector opposite the electron. The results is shown below. Note there are about four times as many counts (good!), but there are several regions where the acceptance depends on ϕ_h which would make fitting the spectrum difficult. No electron fiducial cuts are turned on here.

Fig 1. Hadron acceptance for 2.6 GeV, normal polarity under the conditions described above.

Jerry Gilfoyle's Enotebook page 50 - S3 2-3 gen fits (gpg)

[Modified Thu Jul 28 12:54:16 2005 (GMT) gpg]

Plot of edges from 1gen fits.

[Fig 1.](#) Plot of results of 1gen fits for sector 3.

[Fig 2.](#) Acceptance plot for hadrons for sector 3, 2.6 GeV, normal polarity.

Click [here](#) to view the object (Fit parameters for sector 3 (6/3/5, 10:53)) you uploaded.

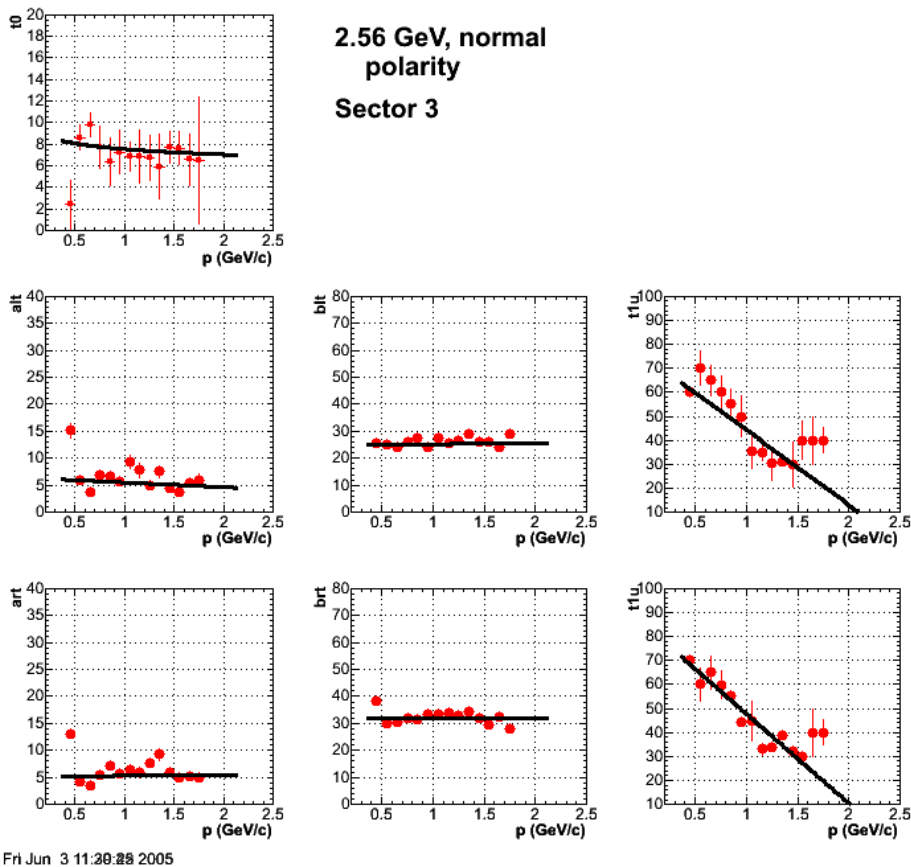

Fig 3. Third generation fits for sector 3. The values of $t1$ were limited to ± 5 degrees of a value of the transition to a flat θ_h dependence that I determined by eye using Fig 2.

[Fig 3b.](#) Plots of 2gen fits associated with Fig 3.

Click [here](#) to view the object (Table of 2gen fit parameters by momentum bin for Fig 3.) you uploaded.

```
gpgl:sector3> grep +++++ pfid_3genpars.out
+++++ fit1 results 7.36413 -0.161796
+++++ fit2 results 6.39853 -0.873738
+++++ fit3 results 25.249 0.032347
+++++ fit4 results 5.18155 0.137108
+++++ fit5 results 31.7698 0.12673
+++++ fit6 results 75.514 -31.2481
+++++ fit7 results 85.0765 -37.3793
g
```

I tried opening up the range available for the value of $t1$, the break point where the θ_h dependence becomes constant. The results are shown in Figure 4. When I let $t1$ vary without limits there is a tendency for Minuit to find a fit with an unphysically large $t1$. The parameter $t1$ can vary a lot with only a small change in the χ^2 . This is not a surprise since you are fitting a region with little dependence on θ_h . Increasing the range for $t1$ to vary doesn't improve the fits much, but it does increase the variation in the other parameters. I'll stick with the smaller $t1$ fit range.

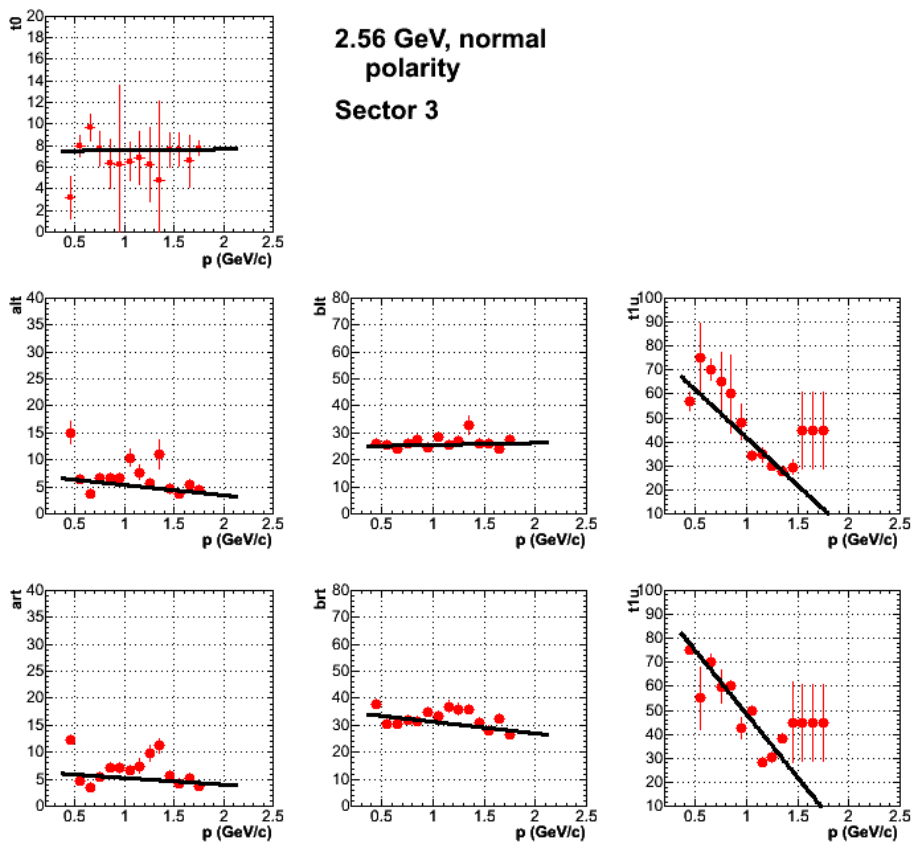

Fig 4. Same as Fig 3 with values of t1 limited to +/- 10 degrees of a value of the transition to a flat theta_h dependence that I determined by eye using Fig 2.

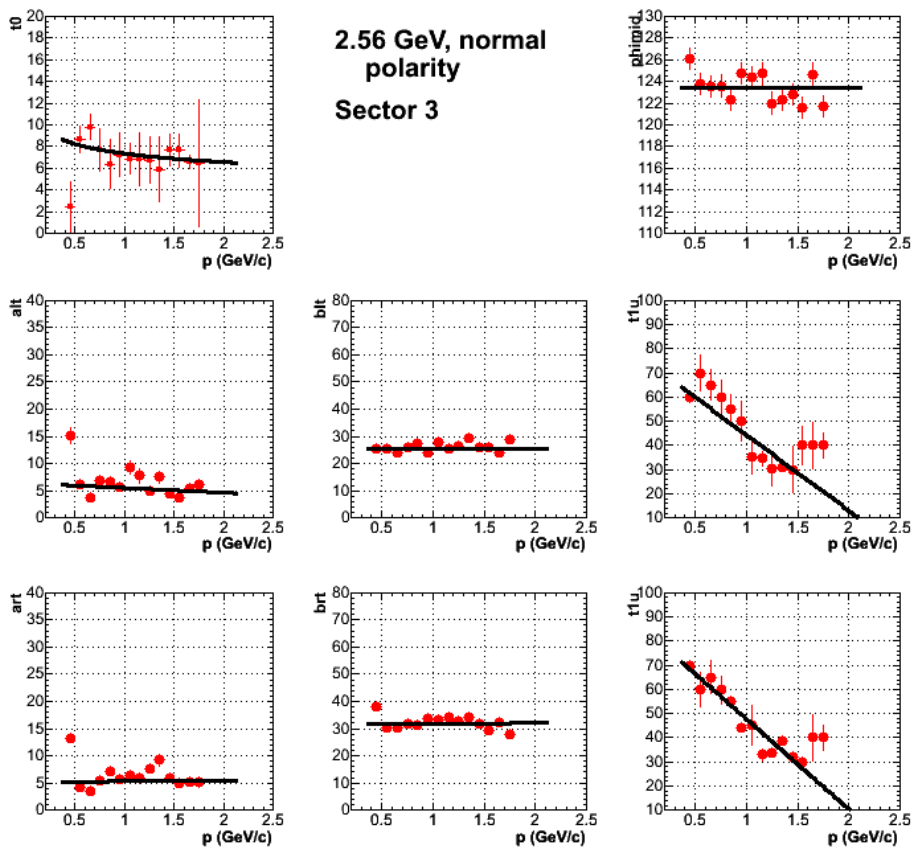

Fig 5. Added phimid to the fits for sector 3, 2.6 GeV, normal polarity

```

Jerry Gilfoyle's Enotebook page 55 - effect of proton fiducial cuts and ALTp at 2.6 GeV, normal polarity (gpg)

[Modified Sun Jan 1 14:40:30 2006 (GMT) gpg I

The first plot below shows a comparison of the hadron acceptance with (left panel) and without (right panel) the hadron fiducial cuts turned on. There are other cuts (electron fiducials, EC fiducials, coplanarity) applied to the plot in the left panel.

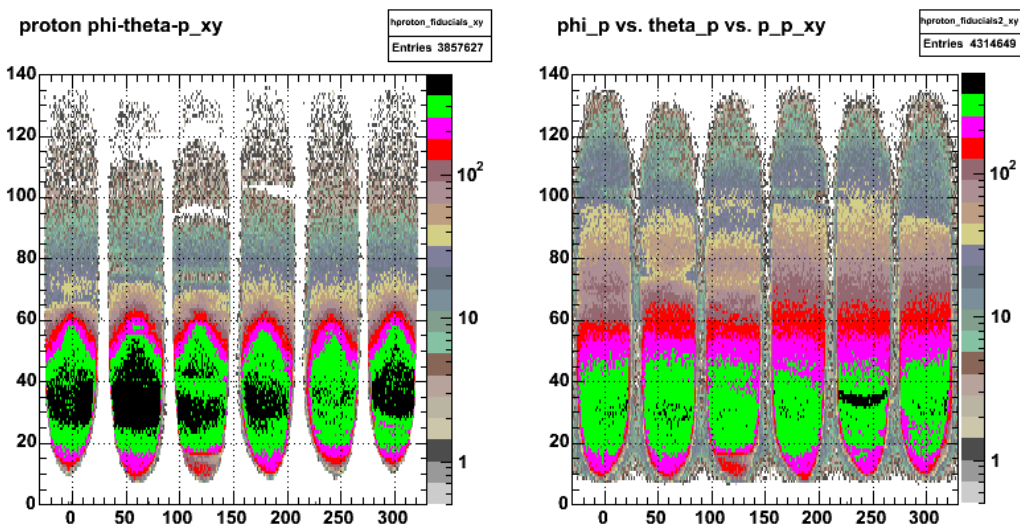

Fig 1. Comparison of hadron acceptance with (left panel) and without (right panel) the hadron fiducial cuts turned on.

The next figure is a cleaner comparison of the effect of the positive hadron fiducial cuts. The only difference in the two panels in Figure 2 is the left-hand panel has the positive hadron fiducial cuts turned on and the right-hand panel has them turned off. Both plots are for protons only with the electron fiducial cuts, EC fiducial cuts, photoelectron, and egiyan cuts turned on. It is worth noting the empty band in sector 3 at around $\theta_p = 90$ deg. This band does not appear when the proton fiducial cuts are turned off. This is likely due to events at very low momentum which are excluded in the left-hand panel because they fell outside the range where we had good measurements of the fiducial region.

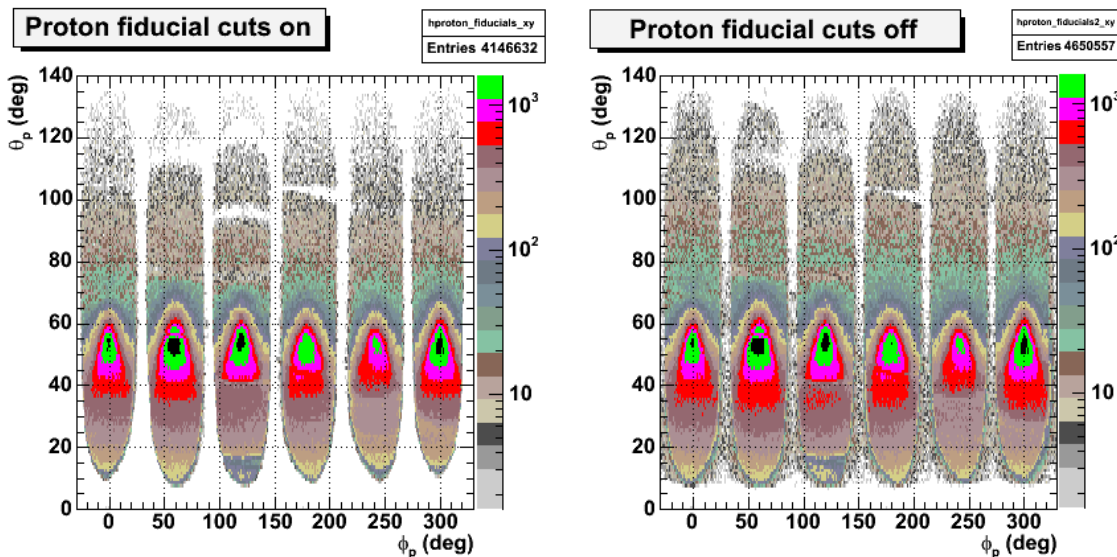

Fig 2. Cleaner comparison of proton acceptance with (left panel) and without (right panel) positive hadron fiducial cuts.

Fig 3. ALTp without the proton fiducial cuts. Compare this with previous results.

Jerry Gilfoyle's Enotebook page 58 - plot of Arenhoevel curves (gpg)

[Modified Wed Jun 15 02:48:14 2005 (GMT) gpg]

Figure below is a combined plot of the Arenhoevel curves that I have. The motivation here is because the change in ALTP when we turn the electron fiducials on seems to be greater than the change predicted by the calculation shown below for a comparable change in the peak value of the Q2 distribution.

Fig 1. Plot of Arenhoevel curves. The number on the right-hand side shows the value of the Q_2 used in the calculation.

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

Jerry Gilfoyle's Enotebook page 59 - another study of electron fiducial cut effects (gpg)

[Modified Wed Jun 15 13:51:02 2005 (GMT) gpg]

In one of the [earlier](#) studies of this effect, we found that the effect on ALTP caused by the electron fiducial cuts was significantly reduced, but not eliminated by requiring $Q^2 > 0.7 \text{ GeV}^2$. To push that test further, we redid the comparison requiring $Q^2 > 1.0 \text{ GeV}^2$. The statistics are noticeably worse, but now all the points on the ALTP distribution are consistent well within the error bars. See the figure below.

2005-06-12 09:53:03

Fig 1. Comparison of ALTP with electron fiducial cuts on (red) and off (blue) requiring $Q^2 > 1.0 \text{ GeV}^2$.

A comparison of the Q^2 distribution is shown below. The electron fiducial cuts have a significant effect on the Q^2 distribution at low Q^2 , but the difference has largely disappeared by the time you reach $Q^2=1.0 \text{ GeV}^2$.

Comparison of Q^2 distribution for 2.6 GeV, normal polarity running with the electron fiducial cuts on (red) and off (blue).

Jerry Gilfoyle's Enotebook page 60 - Rusty's results for momentum corrections at 2.6 GeV, reversed polarity (gpg)**[Modified Tue Jun 21 10:40:07 2005 (GMT) gpg 1**

Below is a tar file with Rusty's results from 2.6 GeV, reversed polarity running.

Q² distribution for electron singles, efid onClick [here](#) to view the object (ROOT C++ macro for Figure 1) you uploaded.Click [here](#) to view the object (ROOT C++ macro for comparing the Q2 distributions at 2.6n with efid on and off) you uploaded.

Jerry Gilfoyle's Enotebook page 62 - KG reversed polarity efids (gpg)

[Modified Thu Jun 23 20:01:21 2005 (GMT) gpg]

Below are plots showing the results of Kristen's extraction of the electron fiducials for the 2.6 GeV reversed field running conditions.

Fig 1. Electron acceptance for 2.6 GeV, reversed polarity with electron fiducial cuts off (left panel) and on (right panel)

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

The C++ routine used to apply the fiducial cuts is below.

```

Int_t eod5::DPelectron_fiducial_cut26r(float Phi_curr, float P_curr, float theta_e_deg)
{
// This function may be called from Loop. it returns 1 if the electron theta and phi
// lie within the fiducial volume. it returns 0 otherwise.
//
// inputs: Phi_curr - azimuthal angle (phi) of the electron in degrees. See note below on the choice of scale.
//          P_curr - momentum of the electron in GeV/c,
//          theta_e_deg - polar angle (theta) of the electron in degrees.
//
// to call this function use something like the following.
//
//          electron_fiducial_status=DPelectron_fiducial_cut26r(phi_e_deg, p[jelectron], theta_e_deg);
//          if (electron_fiducial_status==1) {
//              good_electron_fiducial = true;
//          }
//
// based on method used by dan protopopescu and described at
// http://nuclear.gla.ac.uk/clas/e2doc/FiducialCuts/

Jerry Gilfoyle's Enotebook page 63 - 2.6r pcorr1, Pitt method (gpg)

[Modified Wed Jul 6 15:44:00 2005 (GMT) gpg]

Below are some initial results for the momentum corrections for the 2.6 GeV, reversed polarity settings. In Figure 1, this is our starting point. The parameters used in the momentum-corrected results (right panel) are using the old parameters left over from the 2.6n results.

Comparison of W2 versus phi_e for uncorrected (left panel) and momentum corrected (right panel).

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

Click [here](#) to view the object (Root histogram file for Fig 1) you uploaded.

I use the run above in Fig 1 to generate the new correction factors using the entry 109/Pitt method and rerun things and get Fig 2. There is not much change, but there is some improvement in sectors 5-6. Sector 3 is little changed which is a disappointment since it looks like it could be fixed.

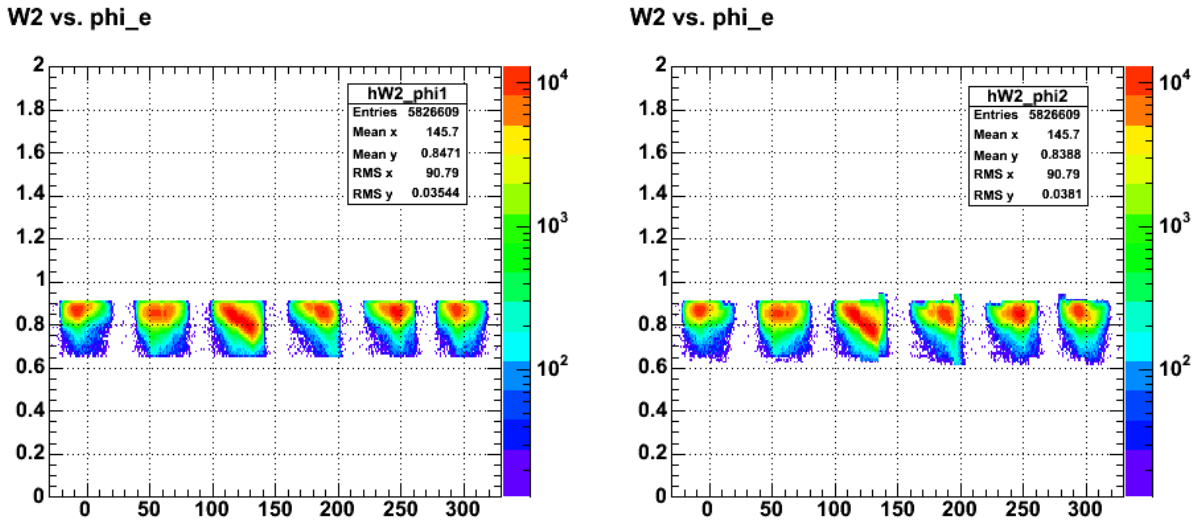

Fig 2. W2 vs. phi_e from just running my old code on the 2.6r data to get the parameters for the momentum correction. The uncorrected momenta is used in the left panel and the corrected electron momentum is used in the right panel.

The plots below show a comparison between some results for the uncorrected and corrected electron momenta. The spectra of W² for ep->eX are shown sector by sector and a gaussian fit is made to the proton peak. The results are rather discouraging. In general, the corrected W2 spectra are infinitesimally WORSE than the corrected ones. The difference is usually negligible. This is similar to what I saw for the 2.6 GeV, normal polarity running conditions and what Jeff Iachniet saw in his analysis. This is, I believe a product of the observation that the uncertainty in the stiffness (qB/p) for the proton tracks is much larger than the stiffness for the electron tracks. This large scatter in the proton stiffness essentially randomizes the fits to the electron results.

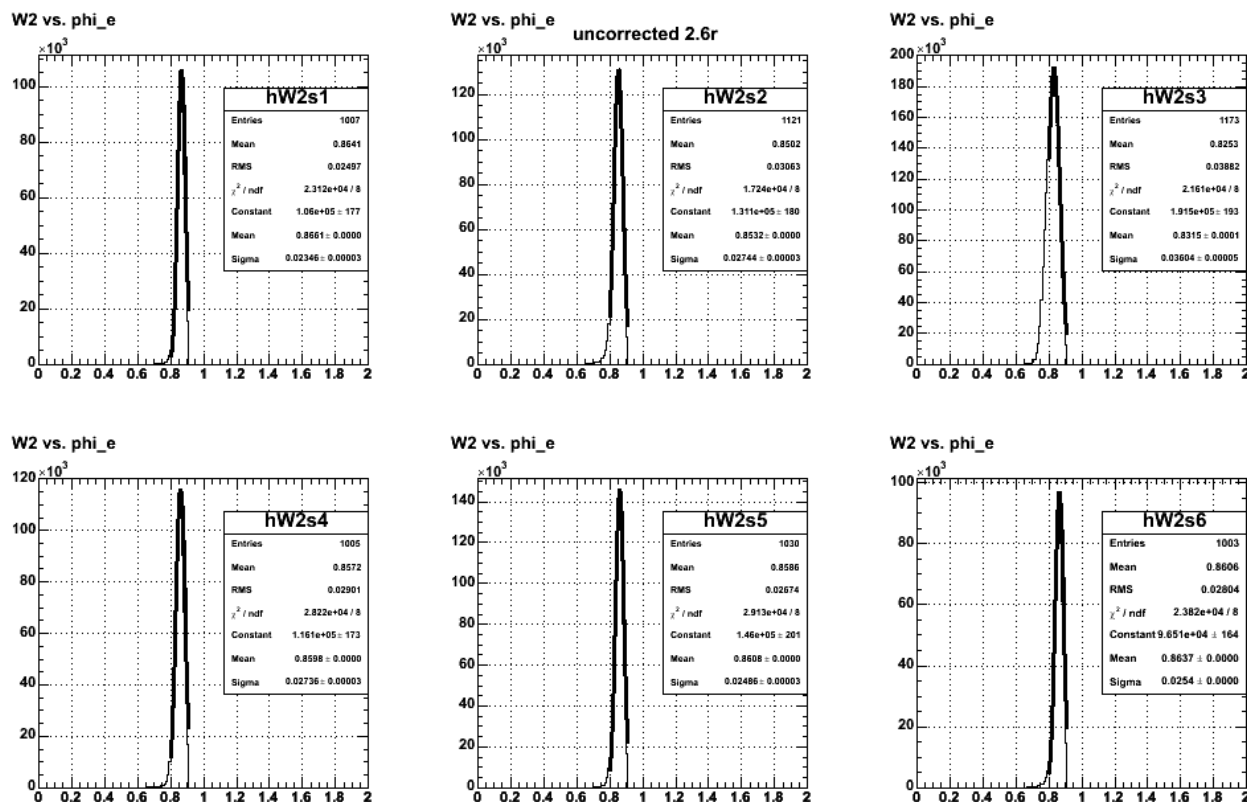

Fig 3. Fits to the uncorrected W^2 spectra sector by sector

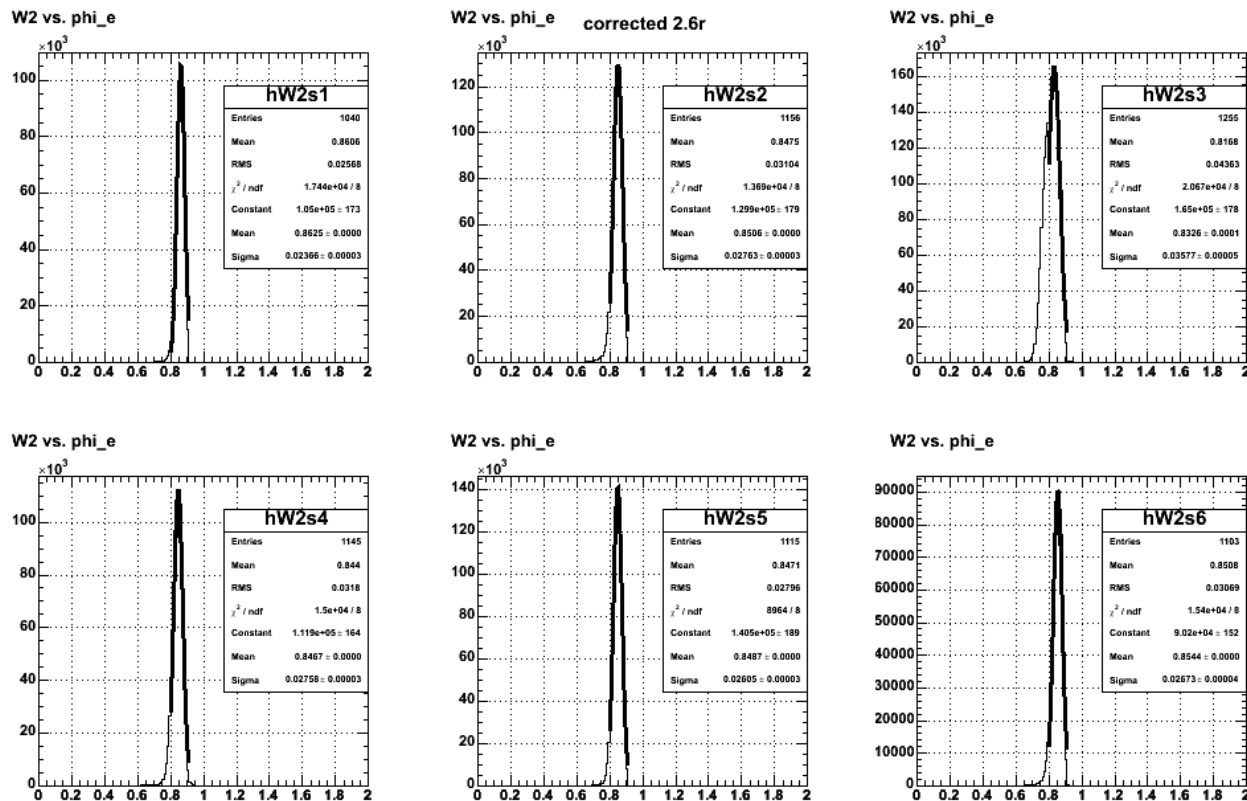

Fig 4. Fits to the corrected W^2 spectra sector by sector

The plots below show the profile histograms and fits used to extract the correction parameters for sector 3 where W2 shows the greatest dependence on ϕ_e (see Figs 1-2).

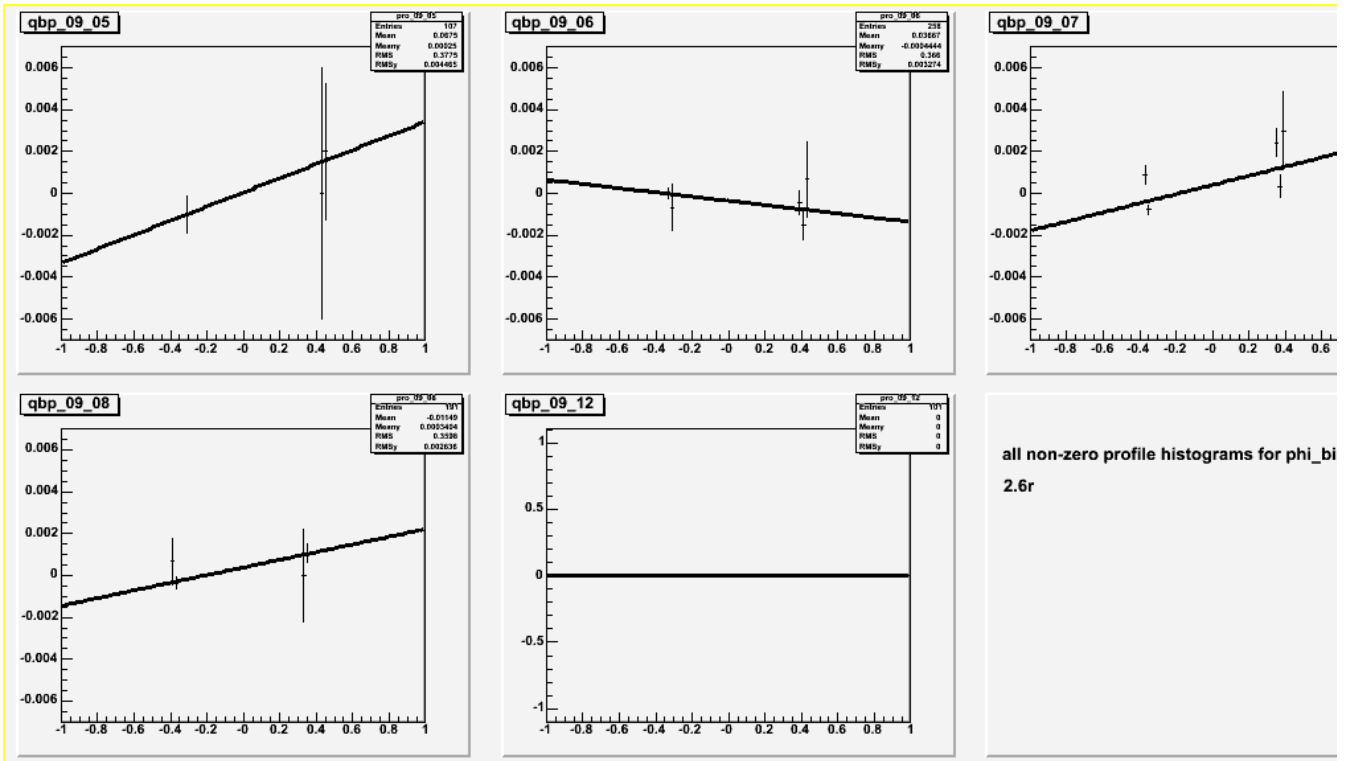

Fig 5. Profile histograms for the region in ϕ_e where W2 shows the greatest variation (sector 3, $\phi_{bin}=9$)

Click [here](#) to view the object (pcorr_ep2.C - C++ class for the Pitt method momentum corrections, first ry with the wrong electron fiducial cuts on.) you uploaded.

I discovered that the analysis run I used to generate the momentum correction parameters above was done for the 2.6r data set using the 2.6n electron fiducial cuts (oops!). Rerun the analysis and I get the following results. The centroid of the W2 distribution improves on most of the sectors (1-5) and is infinitesimally worse on sector 6. That's the good news. The bad news is the width gets worse! It is anywhere from 20-50% larger in the corrected spectra. This is the opposite of the 2.6n results where the centroid moved, but was no better after momentum correction (it went from just below to just above the accepted value) and the width of the corrected spectra was about 20-30% better than the uncorrected spectra (for 2.6n).

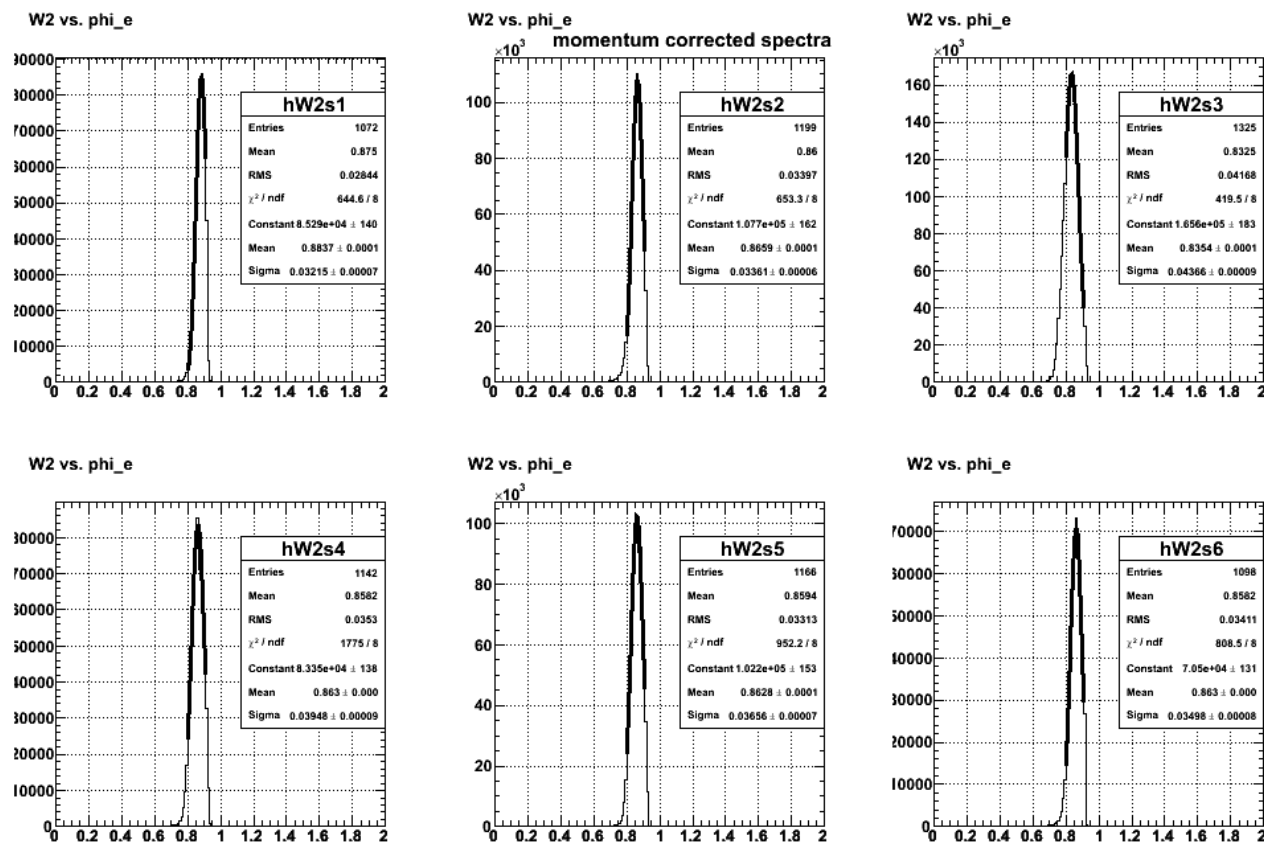

Fig 8. Momentum corrected spectra sector-by-sector for 2.6 GeV, reversed polarity.

The width is noticeably better on sectors 1-3 when I center the fit range on the peak. These sectors now have about the same width as the uncorrected spectra. Sector 3-6 are still worse.

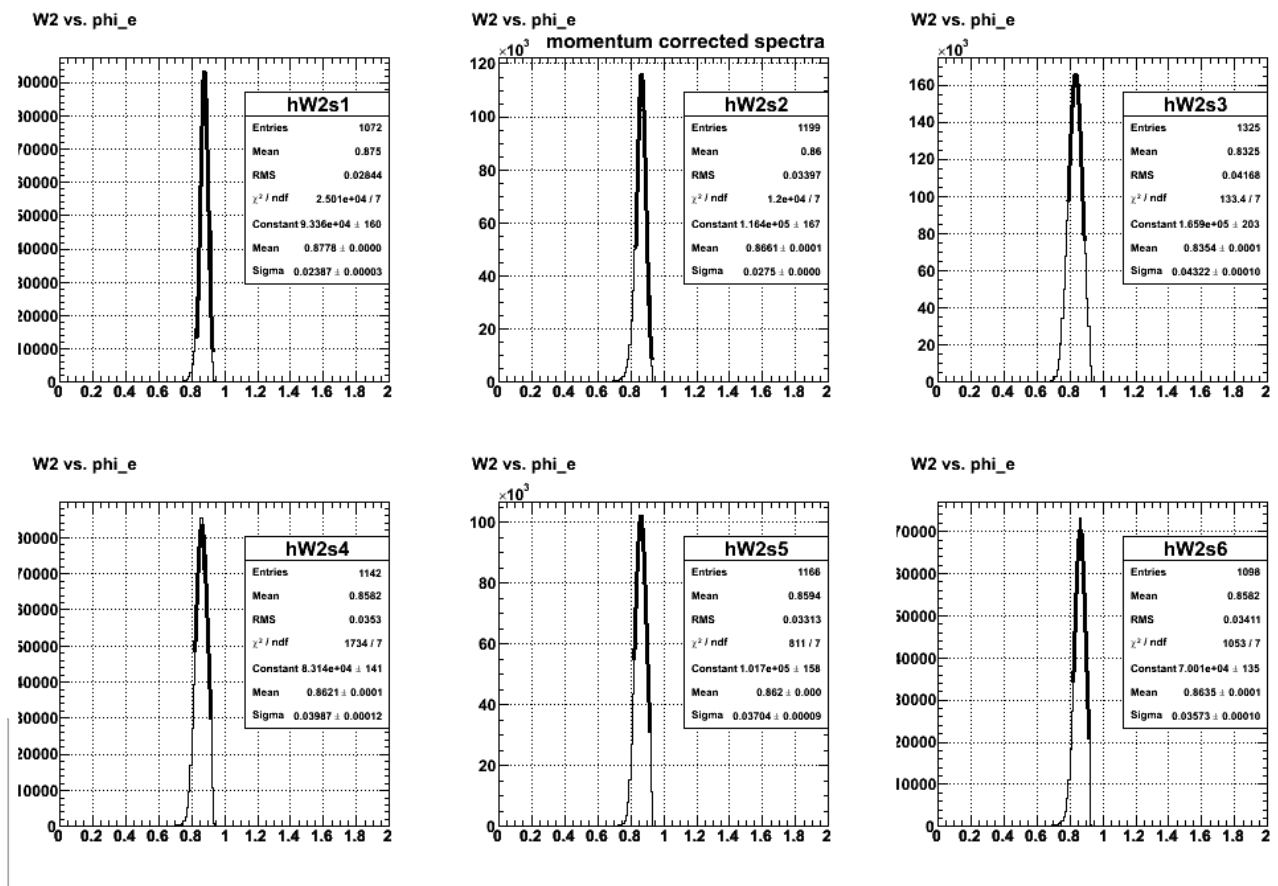

Fig 9. Momentum corrected spectra sector-by-sector for 2.6 GeV, reversed polarity. I centered the fit range better on these spectra.

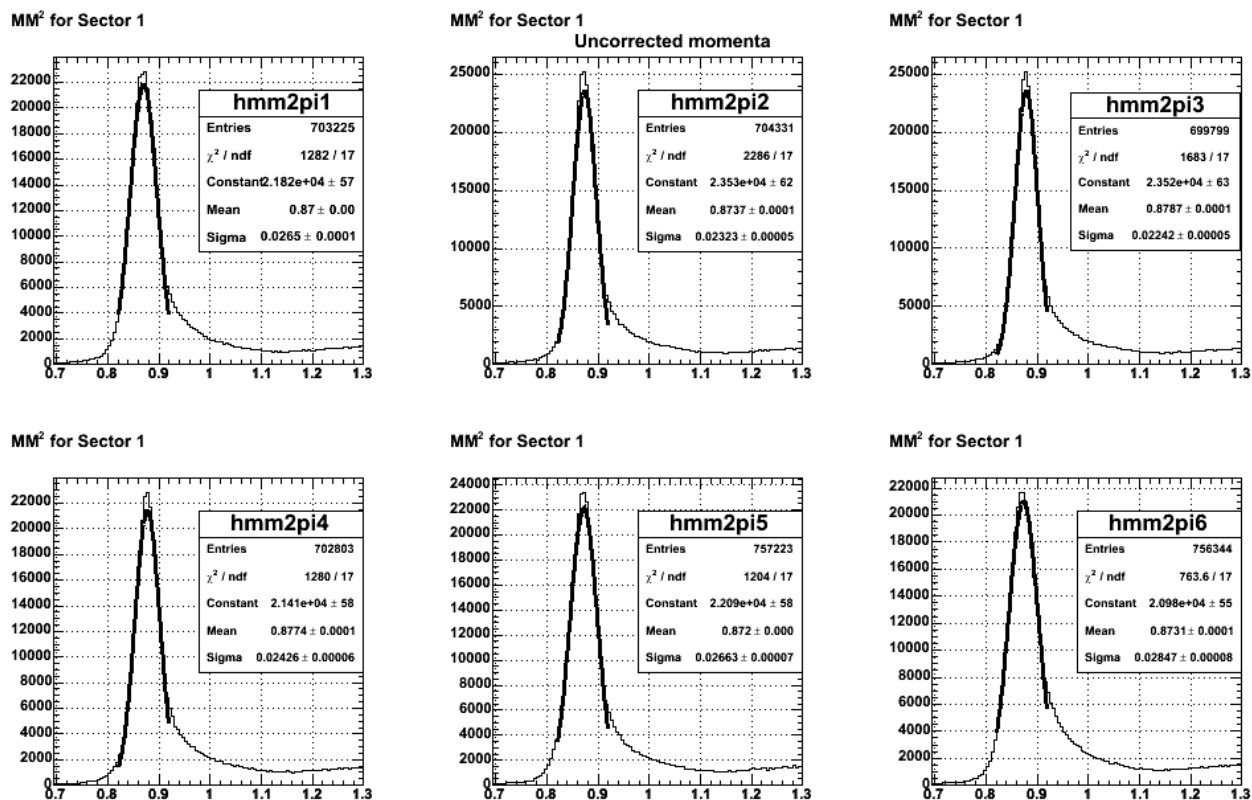

Fig 2. MM2 sector by sector for ep->e'pi+X for 2.6 GeV, reversed polarity and uncorrected momenta. Used finer binning than Fig 1.

Click [here](#) to view the object (ROOT C++ macro for Fig 2.) you uploaded.

Click [here](#) to view the object (ROOT histogram file for Fig 2.) you uploaded.

The plots below show the results using the corrected proton and electron momenta. The corrected results are uniformly WORSE than the uncorrected ones. Even after tuning the range of the gaussian fit this still holds true. The difference is small; a fraction of a percent for the centroid and a few percent for the width, but it is still disappointing. My guess is that barring a software or calculational error, what I'm seeing is the effect of the large uncertainty on the proton's stiffness (qB/p) that was documented in entry 63. A table of the values is below.

sector	uncorrected		corrected	
sector	centroid	width	centroid	width
1	0.8689	0.02384	0.8665	0.02521
2	0.8724	0.02037	0.8704	0.02266
3	0.8775	0.02004	0.8716	0.02299
4	0.8764	0.02165	0.8776	0.02281
5	0.8714	0.02342	0.8751	0.02622
6	0.8716	0.02587	0.8698	0.02741

hmm2pi6->Draw();
hmm2pi6->Fit("gaus","","",0.82,0.92);
```

Jerry Gilfoyle's Enotebook page 65 - VB p_e corrections for 2.6r (gpg)

[Modified Tue Jul 5 15:27:35 2005 (GMT) gpg]

The plot below shows a comparison of W2 for uncorrected electron momenta (left panel) and electron momenta corrected using the Volker Burckhardt (VB) method (right panel).

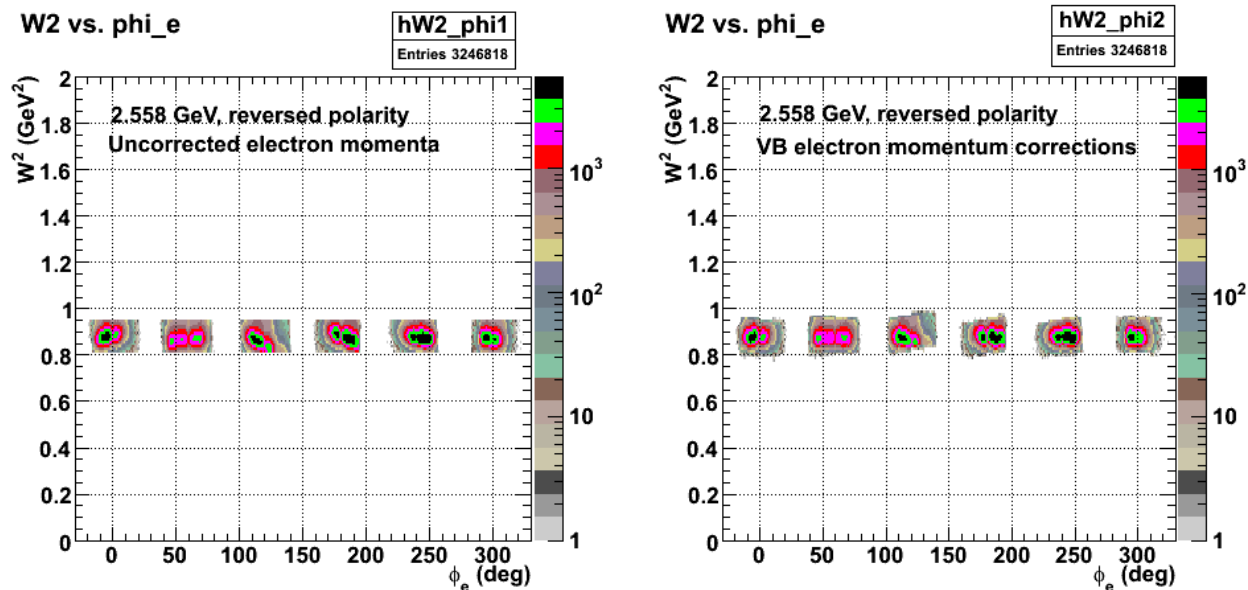

Fig 1. Comparison of W2 for uncorrected electron momenta (left panel) and electron momenta corrected using the VB method (right panel).

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

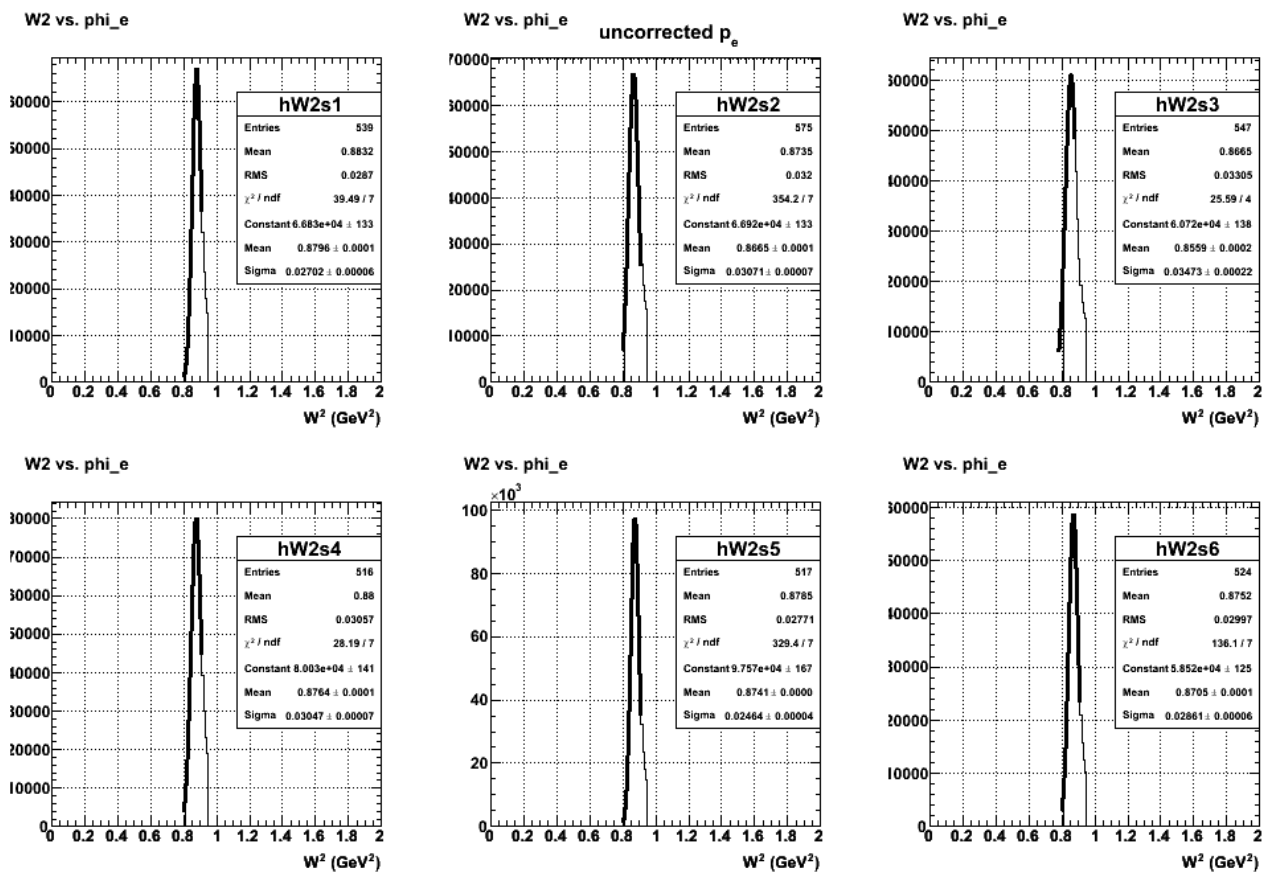

Fig 2. W2 spectra sector-by-sector for uncorrected electron momenta.

Click [here](#) to view the object (ROOT C++ macro for Fig 2.) you uploaded.

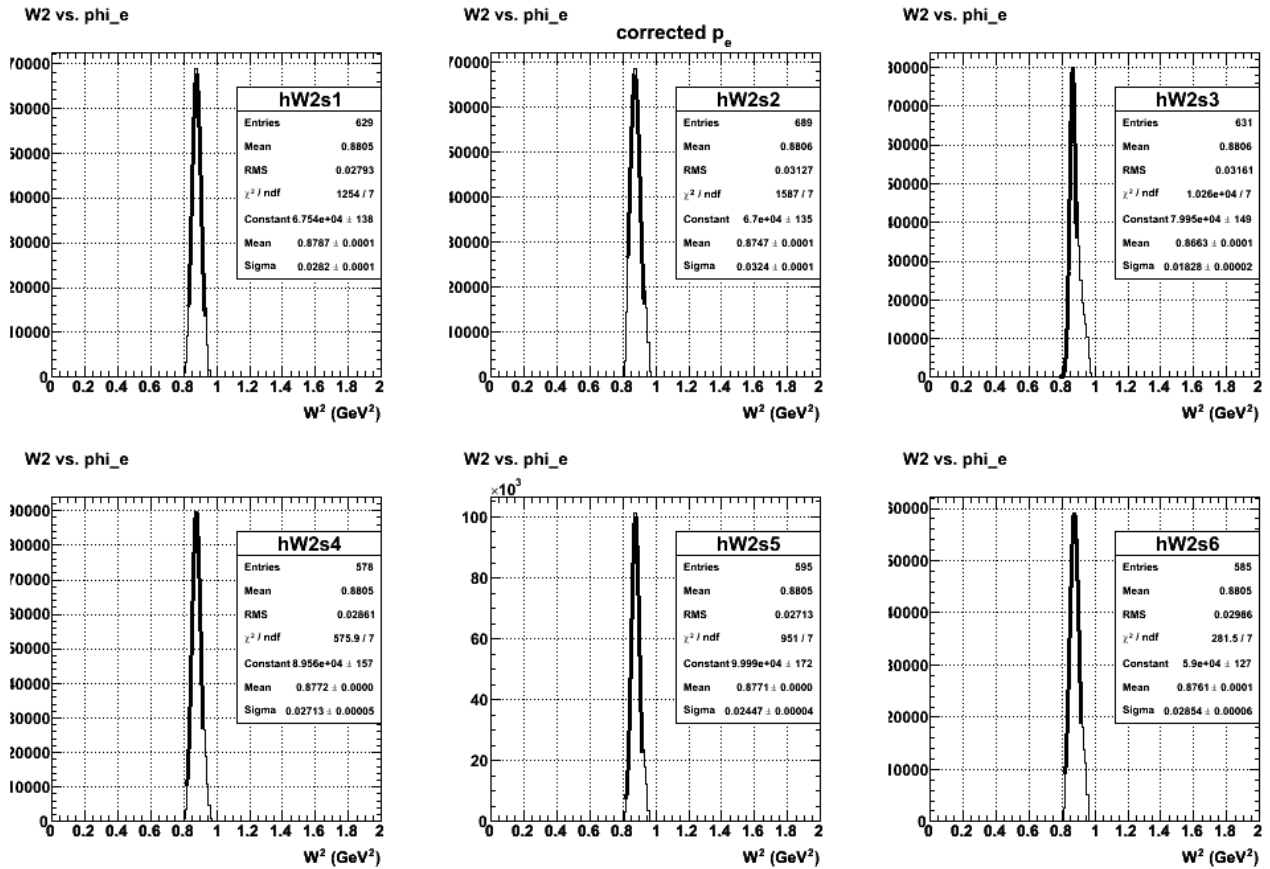

Fig 3. W2 spectra sector-by-sector for corrected electron momenta.

Click [here](#) to view the object (ROOT C++ macro for Fig 3.) you uploaded.

Comparing the corrected and uncorrected W^2 spectra above shows some improvement due to the electron momentum corrections using the VB method. The table below shows the comparison sector-by-sector. Some sectors are infinitesimally worse with the corrections (1), some are better (4,5,6), some are mixed (2), while sector 3 shows a large improvement in the width of the distribution. This shows that some of the sectors (like sector 1) were well calibrated in the first place so the corrections have little effect while other sectors (sector 3) are significantly better after the corrections.

Sector	Uncorrected		Corrected	
	Centroid	Width	Centroid	Width
1	0.8796	0.02702	0.8787	0.02820
2	0.8665	0.03071	0.8747	0.03240
3	0.8559	0.03473	0.8663	0.01828
4	0.8764	0.03047	0.8772	0.02713
5	0.8741	0.02464	0.8771	0.02447
6	0.8705	0.02861	0.8761	0.02854

The ROOT code used to extract the fits sector-by-sector is below. For the uncorrected spectra in hW2_phi1:

```
TCanvas *c1 = new TCanvas("c1", "c1",20,3,1000,700);
c1->Divide(3,2);
gStyle->SetOptFit(1);
gStyle->SetStatH(0.30);
gStyle->SetStatW(0.35);
gStyle->SetStatX(0.90);
gStyle->SetStatY(0.80);
TH2D *hw2s1 = (TH2D*)hw2_phi1->Clone();
TH2D *hw2s2 = (TH2D*)hw2_phi1->Clone();
TH2D *hw2s3 = (TH2D*)hw2_phi1->Clone();
TH2D *hw2s4 = (TH2D*)hw2_phi1->Clone();
TH2D *hw2s5 = (TH2D*)hw2_phi1->Clone();
TH2D *hw2s6 = (TH2D*)hw2_phi1->Clone();
int philo, phihi;
philo=1;
phihi=60;
TH1D *h2as1 = (TH1D*) hw2s1->ProjectionY("hw2s1",philo,phihi);
c1_1->cd();
h2as1->Draw();
h2as1->Fit("gaus", "", "", 0.80, 0.91);
philo=61;
phihi=120;
TH1D *h2as2 = (TH1D*) hw2s2->ProjectionY("hw2s2",philo,phihi);
c1_2->cd();
```

```

h2as2->Draw();
h2as2->Fit("gaus", "", "", 0.80, 0.91);
philo=121;
phihi=180;
TH1D *h2as3 = (TH1D*) hW2s3->ProjectionY("hW2s3", philo, phihi);
c1_3->cd();
h2as3->Draw();
h2as3->Fit("gaus", "", "", 0.78, 0.88);
philo=181;
phihi=240;
TH1D *h2as4 = (TH1D*) hW2s4->ProjectionY("hW2s4", philo, phihi);
c1_4->cd();
h2as4->Draw();
h2as4->Fit("gaus", "", "", 0.80, 0.91);
philo=241;
phihi=300;
TH1D *h2as5 = (TH1D*) hW2s5->ProjectionY("hW2s5", philo, phihi);
c1_5->cd();
h2as5->Draw();
h2as5->Fit("gaus", "", "", 0.80, 0.91);
philo=301;
phihi=360;
TH1D *h2as6 = (TH1D*) hW2s6->ProjectionY("hW2s6", philo, phihi);
c1_6->cd();
h2as6->Draw();
h2as6->Fit("gaus", "", "", 0.80, 0.91);

```

For the corrected spectra in hW2_phi2:

```

TCanvas *c1 = new TCanvas("c1", "c1", 20, 3, 1000, 700);
c1->Divide(3, 2);
gStyle->SetOptFit(1);
gStyle->SetStatH(0.30);
gStyle->SetStatW(0.35);
gStyle->SetStatX(0.90);
gStyle->SetStatY(0.80);
TH2D *hW2s1 = (TH2D*) hW2_phi2->Clone();
TH2D *hW2s2 = (TH2D*) hW2_phi2->Clone();
TH2D *hW2s3 = (TH2D*) hW2_phi2->Clone();
TH2D *hW2s4 = (TH2D*) hW2_phi2->Clone();
TH2D *hW2s5 = (TH2D*) hW2_phi2->Clone();
TH2D *hW2s6 = (TH2D*) hW2_phi2->Clone();
int philo, phihi;
philo=1;
phihi=60;
TH1D *h2as1 = (TH1D*) hW2s1->ProjectionY("hW2s1", philo, phihi);
c1_1->cd();
h2as1->Draw();
h2as1->Fit("gaus", "", "", 0.83, 0.93);
philo=61;
phihi=120;
TH1D *h2as2 = (TH1D*) hW2s2->ProjectionY("hW2s2", philo, phihi);
c1_2->cd();
h2as2->Draw();
h2as2->Fit("gaus", "", "", 0.83, 0.93);
philo=121;
phihi=180;
TH1D *h2as3 = (TH1D*) hW2s3->ProjectionY("hW2s3", philo, phihi);
c1_3->cd();
h2as3->Draw();
h2as3->Fit("gaus", "", "", 0.79, 0.89);
philo=181;
phihi=240;
TH1D *h2as4 = (TH1D*) hW2s4->ProjectionY("hW2s4", philo, phihi);
c1_4->cd();
h2as4->Draw();
h2as4->Fit("gaus", "", "", 0.82, 0.92);
philo=241;
phihi=300;
TH1D *h2as5 = (TH1D*) hW2s5->ProjectionY("hW2s5", philo, phihi);
c1_5->cd();
h2as5->Draw();
h2as5->Fit("gaus", "", "", 0.82, 0.92);
philo=301;
phihi=360;
TH1D *h2as6 = (TH1D*) hW2s6->ProjectionY("hW2s6", philo, phihi);
c1_6->cd();
h2as6->Draw();
h2as6->Fit("gaus", "", "", 0.82, 0.92);

```

The C++ function used in the analysis code to apply the momentum corrections for the 2.6 GeV, reversed field data is below.

```

Float_t ep1::JLpcorr26r(float p_e_in, float phi_e, float theta_e)
{
    // this function corrects the electron momentum using the VB method for the 2.6 GeV, reversed
    // torus polarity setting.

    // user variables.
    int pcorr_theta_bin, pcorr_phi_bin;
    float p_e_out;

    // inputs
    float alpha[16][36] = {
        0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0,
        0, 0, 0, 0, 0, 0, 0,
    };
}

```

```

Some months later, i reran the analysis for the 2.6r data set and got the plots below. I do not understand why the uncertainties are so much smaller than the figures above. Nevertheless, this looks quite pretty!

Jerry Gilfoyle's Enotebook page 68 - JML curves (gpg)

[Modified Fri Sep 2 19:32:59 2005 (GMT) gpg]

Jean-Marc Laget has made some calculations of ALTp using his code described in a recent paper (PLB, 609 (2005) 49-56). Calculations have been done as a function of missing momentum p_m at three values of Q^2 (0.70 GeV², 1.13 GeV², and 1.55 GeV²) for a beam energy of 2.558 GeV. The results are shown in Figure 1. There is a sharp dip at $p_m \sim 0.28$ GeV/c for $Q^2=0.7$ GeV² which drops off at the higher Q^2 . The change in shape of ALTp is more rapid than what we have seen in calculations by [Arenhoevel](#) and shown in Figure 2.

Wed Jul 27 20:55:09 2005

Fig 1. Comparison of JML calculations at different Q^2 .

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

The Arenhoevel calculation changes more slowly across a larger Q^2 range than the Laget calculation. This may not be a surprise since the limit of the validity of the Arenhoevel calculation is $Q^2 \sim 1$ GeV².

Fig 2. H.Arenhoevel calculation of ALp as a function of missing momentum for 2.58 GeV

We have used the three calculations above to roughly average the Laget calculations over the Q^2 distribution for the 2.6 GeV, normal torus polarity data. The results are shown in Fig 3. There is a dip in ALp in the data at $p_m = 0.24$ GeV/c which is not as wide as the Laget calculation and then a rise in the asymmetry at larger missing momentum that is not reproduced by the calculation.

Fig 3. JML curve averaged roughly over Q^2 and compared with 2.6 GeV, normal polarity data.

Click [here](#) to view the object (ROOT C++ macro file ALTp2.C for Fig 3.) you uploaded.

Below is a comparison of the JML and HA calculations averaged over Q^2 . Both show a dip at or near $p_m=0.28$ GeV/c. Could this feature reflect some underlying physics. I sent JML an email asking this question.

Jerry Gilfoyle's Enotebook page 69 - Effect of electron momentum corrections on ALTp for 2.6r (gpg)

[Modified Fri Jul 8 05:48:42 2005 (GMT) gpg]

The plot below shows the effect of the electron momentum corrections on the fifth-structure-function asymmetry for the 2.6 GeV, reversed field polarity running conditions.

2005-07-08 01:46:08

Fig 1. Comparison of ALTp with electron momentum corrections on (red) and off (blue) for 2.6r running conditions.

Jerry Gilfoyle's Enotebook page 70 - testing neutron ID (gpg)

[Modified Tue Jul 19 04:38:40 2005 (GMT) gpg]

The plots below are the start of my analysis of the neutron ID.

[Fig 1.](#) Plot of N^- vs. p_m for $wgt=1$. Binning matches the usual binning for extracting ALTp.

[Fig 2.](#) Plot of N^+ vs. p_m for $wgt=1$. Binning matches the usual binning for extracting ALTp.

[Fig 3.](#) Plot of N^+ vs. p_m for $wgt=\sin(\phi_{pq})$. Binning matches the usual binning for extracting ALTp.

[Fig 4.](#) Plot of N^- vs. p_m for $wgt=\sin(\phi_{pq})$. Binning matches the usual binning for extracting ALTp.

Comparison of ALTp for 2.6 GeV, normal polarity extracted using the usual method (right panel) and projecting it out of a 2D mm2 vs. N histogram and then calculating ALTp (left panel). The code for extracting ALTp with the 2D projection method is below. The problems are obvious. Also I don't think the calculation of uncertainties in either plot is particularly trustworthy at the moment.

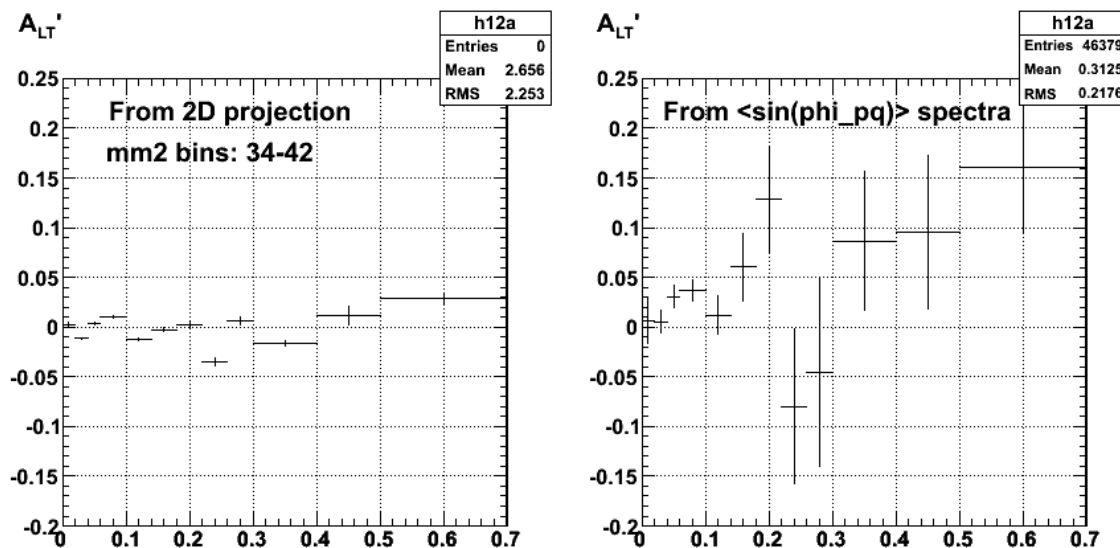

Fig 5. Comparison of ALTp for 2.6 GeV, normal polarity extracted using the usual method (right panel) and projecting it out of a 2D mm2 vs. N histogram and then calculating ALTp (left panel).

ROOT C++ macro for creating one of the input histograms for ALTp using the 2D projection method.

```
mm2bin=1;
TH1D *h1 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h1",mm2bin,mm2bin);
mm2bin=2;
TH1D *h2 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h2",mm2bin,mm2bin);
mm2bin=3;
TH1D *h3 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h3",mm2bin,mm2bin);
mm2bin=4;
TH1D *h4 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h4",mm2bin,mm2bin);
mm2bin=5;
TH1D *h5 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h5",mm2bin,mm2bin);
mm2bin=6;
TH1D *h6 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h6",mm2bin,mm2bin);
mm2bin=7;
TH1D *h7 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h7",mm2bin,mm2bin);
mm2bin=8;
TH1D *h8 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h8",mm2bin,mm2bin);
mm2bin=9;
TH1D *h9 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h9",mm2bin,mm2bin);
mm2bin=10;
TH1D *h10 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h10",mm2bin,mm2bin);
mm2bin=11;
TH1D *h11 = (TH1D*) hmm2_p_m_unwghtplus->ProjectionY("h11",mm2bin,mm2bin);

c1_1->cd()
h1->Draw()
c1_2->cd()
h2->Draw()
c1_3->cd()
h3->Draw()
c1_4->cd()
h4->Draw()
c1_5->cd()
h5->Draw()
c1_6->cd()
```

```

h6->Draw()
c1_7->cd()
h7->Draw()
c1_8->cd()
h8->Draw()
c1_9->cd()
h9->Draw()
c1_10->cd()
h10->Draw()
c1_11->cd()
h11->Draw()

c1_12->cd()
c1_12->Range(0.375, -37.3026, 1.625, 273.553);

tex = new TLatex(0.556593, 193.813, "2.6 GeV");
tex->SetTextSize(0.1);
tex->SetLineWidth(2);
tex->Draw();

tex = new TLatex(0.540322, 155.387, "Normal polarity");
tex->SetTextSize(0.1);
tex->SetLineWidth(2);
tex->Draw();

tex = new TLatex(0.540322, 111.721, "h=+1");
tex->SetTextSize(0.1);
tex->SetLineWidth(2);
tex->Draw();

```

Once you have the histograms use the following ROOT macro to get ALTp.

```

mm2binlo=34;
mm2binhi=42;
TH1D *huplus = (TH1D*) hmm2_p_m_unwghtplus->ProjectionX("huplus", mm2binlo, mm2binhi);
TH1D *huminus = (TH1D*) hmm2_p_m_unwghtminus->ProjectionX("huminus", mm2binlo, mm2binhi);
TH1D *hwminus = (TH1D*) hmm2_p_m_sin_phi_wghtminus->ProjectionX("hwminus", mm2binlo, mm2binhi);
TH1D *hwplus = (TH1D*) hmm2_p_m_sin_phi_wghtplus->ProjectionX("hwplus", mm2binlo, mm2binhi);

int n_varp_mbins = 12;
Float_t p_m_bin_edges[13]={0.0,0.02,0.04,0.06,0.10,0.14,0.18,0.22,0.26,0.30,0.40,0.50,0.70};
TH1F *h1a = new TH1F("h1a", "Sin(#phi) weighted distribution for positive helicity", n_varp_mbins, p_m_bin_edges);
TH1F *h2a = new TH1F("h2a", "Sin(#phi) weighted distribution for negative helicity", n_varp_mbins, p_m_bin_edges);
h1a.Sumw2();
h2a.Sumw2();
h1a.Divide(hwplus, huplus);
h2a.Divide(hwminus, huminus);
TH1F *h12a = new TH1F("h12a", "A_{LT}", n_varp_mbins, p_m_bin_edges);
h12a.Sumw2();
h12a.Add(h1a, h2a, 1.0, -0.9994);
h12a.Draw();

```

Fix some stuff (i.e. both should have QE cut!) and things looks much better. This still have to be improved because these two methods should agree exactly since they come from the same data.

Fig 6. Comparison of ALTp for 2.6 GeV, normal polarity extracted using the usual method (red) and projecting it out of a 2D mm2 vs. N histogram and then calculating ALTp (black).

Some more tests. Compare the different spectra going into the calculation of ALTp when using the mm2 cut or projecting them out from the mm2 2D histogram.

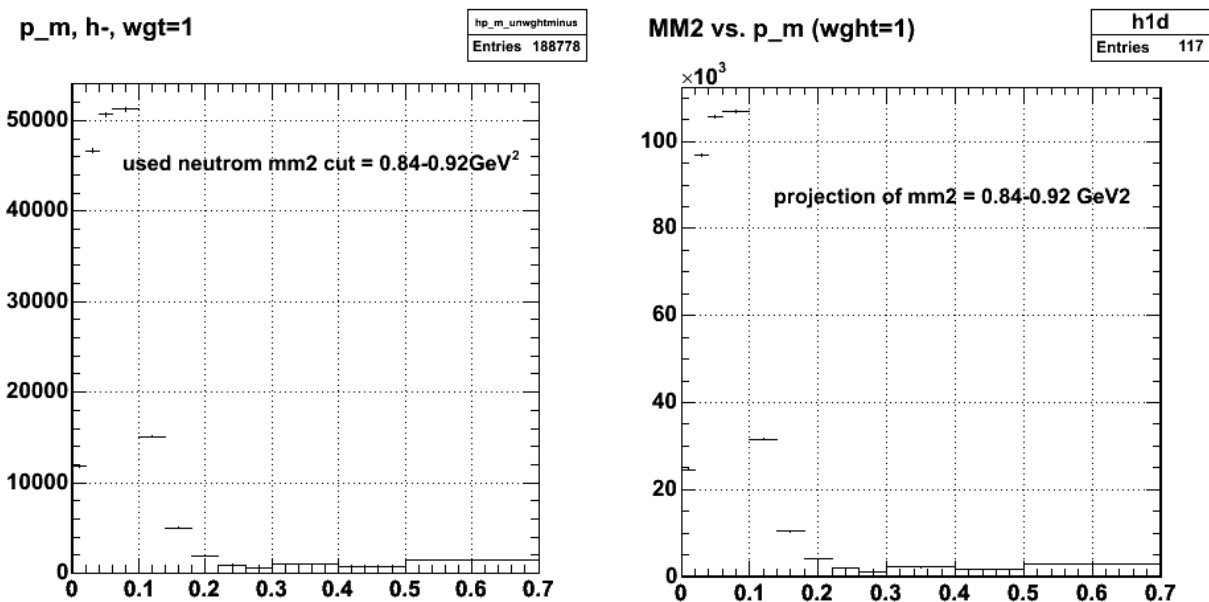

Fig 9. Comparison of the wght=1 spectra N- for the mass cut $mm2=0.84-0.92$ GeV² (left panel) and the projection from the 2D $mm2$ vs. p_m using $mm2=0.84-0.92$ GeV² (right panel)

Click [here](#) to view the object (ROOT C++ macro for Fig 9.) you uploaded.

Click [here](#) to view the object (ROOT histogram file used for Fig 9.) you uploaded.

Change the way the weights are handled when the histograms are incremented from sumW2 to simple addition of the weights. The ROOT histogram file is just below.

Click [here](#) to view the object (Root histogram file containing histograms WITHOUT sumW2 for the 2D $mm2$ vs. p_m hists like used in Fig 9.) you uploaded.

Jerry Gilfoyle's Enotebook page 71 - Rusty's results for 2.6r pcorr (gpg)

[Modified Thu Jul 21 14:49:45 2005 (GMT) gpg]

Rusty has generated the following results for the 2.6 GeV, reversed field, momentum corrections using the Pitt method. The table below shows his results for the W2 spectra sector by sector for the reaction $ep \rightarrow eX$ and fitting the proton peak.

The results below are for the missing mass of the reaction $ep \rightarrow \pi^+X$ and fitting the neutron peak.

The routine he wrote is below.

```
Double_t eod5::pcorr_RB26r(Float_t pmeas, Float_t theta_ep, Float_t phi_ep, Float_t q_ep)
{
  // This function corrects the electron and proton momenta.

  Double_t pcorr, bee, qbpmeas, qbpmeas_e, alpha, beta;
  int tbin, phibin;

  // constants

  Double_t torus_current=2250.0;

  // array of fit results - 24 phi bins, 16 theta bins, 9 quantities
  // each element has theta, theta_bin, phi, phi_bin, y-int, d(y-int), slope, d(slope), chisquare

  float testunc, testcor, diff, pce, calccore, diff1, diff2;
  float fit_results[24][16][9]={
    {
      //new array 6-21-05 uncorrected momentum, "straight" eod5.C (straight = PDGproton really is proton)

      {7, 0, 0, 0, 0, 0, 0, 0, 0},

Jerry Gilfoyle's Enotebook page 72 - tests of 4.2 GeV efids (gpg)

[Modified Fri Sep 9 02:48:38 2005 (GMT) gpg]

Tests of 4.2 GeV efids are below.

Click [here](#) to view the object (Fig 1. Electron acceptance plot with efids OFF (despite the labeling of the plot) at 4.2 GeV) you uploaded.

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

Click [here](#) to view the object (Fig 2. Electron acceptance plot with efids ON at 4.2 GeV, sector 1) you uploaded.

Looking at the code I realized that the requirement that all events be greater than t_0 (the angle where the singularity occurs in the function defining the edge of the stable acceptance region) had been turned off. Turning it back on cleared up the small number of errant events seen in Fig 2.

Click [here](#) to view the object (Fig 3. Electron acceptance plot, sector 1.) you uploaded.

Click [here](#) to view the object (Fig 4. Electron acceptance plot, sector 2.) you uploaded.

Click [here](#) to view the object (Fig 5. Electron acceptance plot, sector 3.) you uploaded.

Click [here](#) to view the object (Fig 6. Electron acceptance plot, sector 4.) you uploaded.

Click [here](#) to view the object (Fig 7. Electron acceptance plot, sector 5.) you uploaded.

Click [here](#) to view the object (Fig 8. Electron acceptance plot, sector 6.) you uploaded.

Fig 9. Plot of electron acceptance showing effect of turning efids on for 4.2 GeV.

Click [here](#) to view the object (ROOT C++ macro for Fig 9) you uploaded.

Jerry Gilfoyle's Enotebook page 73 - ALTp at 4.2 GeV (gpg)

[Modified Mon Jan 2 22:42:16 2006 (GMT) gpg]

Plots below related to ALTp at 4.2 GeV setting of the E5 data set.

Fig 1. Initial pass at ALTp. This plot has way too few counts in it!!

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

Fig 2. Distribution of Q^2 for 4.2 GeV electron singles events. Electron fiducial cuts are on

To try to improve the statistics, I expanded the bin sizes to that shown in Fig 3. There is still a nagging hint of structure at large p_m , but the statistics are lousy.

Click [here](#) to view the object (ROOT C++ macro for Fig 2) you uploaded.

Click [here](#) to view the object (Latest (7/29/05:13:57 version of histogram file for ALTp that I haven't analyzed yet.) you uploaded.

Fig 3. Same as Figure 1 with different bin sizes.

Click [here](#) to view the object (ROOT C++ macro for Fig 3) you uploaded.

In an attempt to improve the statistics, I have starting removing kinematics cuts. The Figure below shows the result of turning off the electron fiducials. Basically, A_{LT} is zero here.

Fig 4. Same as Figure 1 with electron fiducial cuts turned off to increase the number of counts.

Click [here](#) to view the object (ROOT C++ macro for Fig 4) you uploaded.

2005-09-05 20:52:38
Fig 5. ALTp for 4.2 GeV with all the cuts off except QE, the number of photoelectron (N>25), and the target and event selection

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

2008-01-02 17:37:87
Fig 6. Comparison of QE ALTp for efids pfids on (red) and off(blue).

Click [here](#) to view the object (ROOT C++ macro for Fig 6) you uploaded.

Click [here](#) to view the object (ROOT histogram fiel for Fig 6.) you uploaded.

Jerry Gilfoyle's Enotebook page 74 - code to fit W2 spectra (gpg)

[Modified Fri Jul 29 20:10:40 2005 (GMT) gpg]

Code below is to fit W2 spectra to test effect of momentum corrections.

```
TCanvas *c1 = new TCanvas("c1", "c1",40,5,1000,700);
c1->Divide(3,2);
gStyle->SetOptFit(1);
gStyle->SetStatW(0.40);
gStyle->SetStatH(0.40);
gStyle->SetStatX(0.90);
gStyle->SetStatY(0.850);
float W2lo=0.82, W2hi=0.92;
int rlo=41, rhi=200;
int philo, phihi;
c1_1->cd();
c1_1->SetLeftMargin(0.15);
philo = 1;
phihi = 60;
W2lo = 0.81;
W2hi = 0.92;
TH1F *hs1 = (TH1F*) hW2_phil->ProjectionY("hs1",philo,phihi);
hs1->GetXaxis()->SetRange(rlo, rhi);
hs1->Draw();
hs1->Fit("gaus", "", "", W2lo, W2hi);
c1_2->cd();
c1_2->SetLeftMargin(0.15);
philo = 61;
phihi = 120;
W2lo = 0.75;
W2hi = 0.92;
TH1F *hs2 = (TH1F*) hW2_phil->ProjectionY("hs1",philo,phihi);
hs2->GetXaxis()->SetRange(rlo, rhi);
hs2->Draw();
hs2->Fit("gaus", "", "", W2lo, W2hi);
tex = new TLatex(1.0,30.0,"4.2 GeV, uncorrected");
tex->SetTextFont(132);
tex->SetTextSize(0.05);
tex->SetLineWidth(2);
tex->Draw();
c1_3->cd();
c1_3->SetLeftMargin(0.15);
philo = 121;

Jerry Gilfoyle's Enotebook page 75 - my pcorr1 at 4.2 GeV (gpg)

[Modified Tue Aug 2 18:44:38 2005 (GMT) gpg]

Below are some results of looking at pcorr1 momentum corrections (Pitt methods).

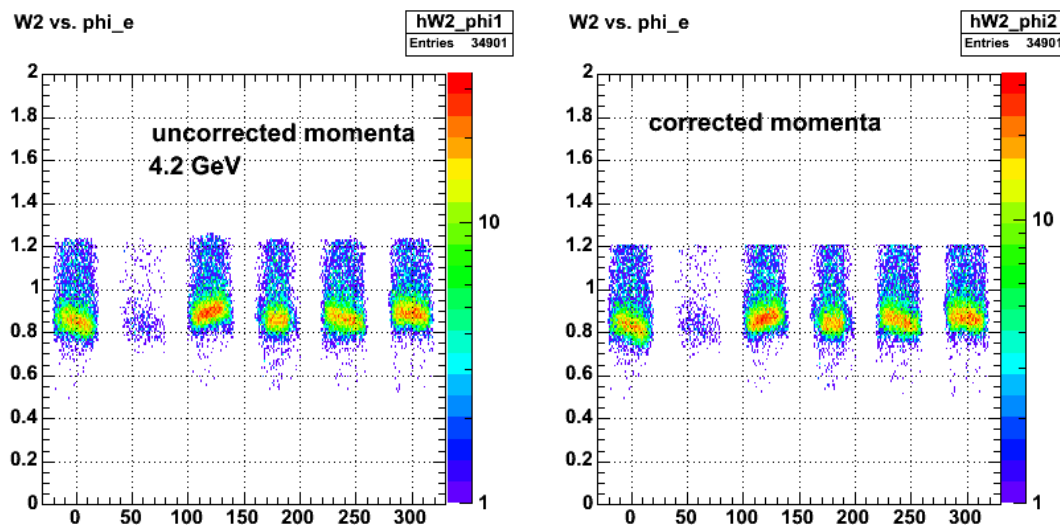

Fig 1. W^2 vs. ϕ_e for uncorrected (left panel) and corrected (right panel) electron momentum from Pitt methods, 4.2 GeV.

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

Results from fitting the W^2 spectrum sector by sector. Basically, they suck. The corrected centroids and widths are worse than the uncorrected ones! For the second shot at them I think I turned off the electron fiducials.

Table 1.

Sector	uncorrected		corrected #1		corrected #2	
	centroid	width	centroid	width	centroid	width
1	0.8488	0.04771	0.7988	0.06696	0.8220	0.05663
2	0.8322	0.05290	0.8391	0.05604	0.8267	0.06079
3	0.8929	0.03687	0.9031	0.05069	0.8625	0.04217
4	0.8575	0.04060	0.8237	0.05855	0.8336	0.05265

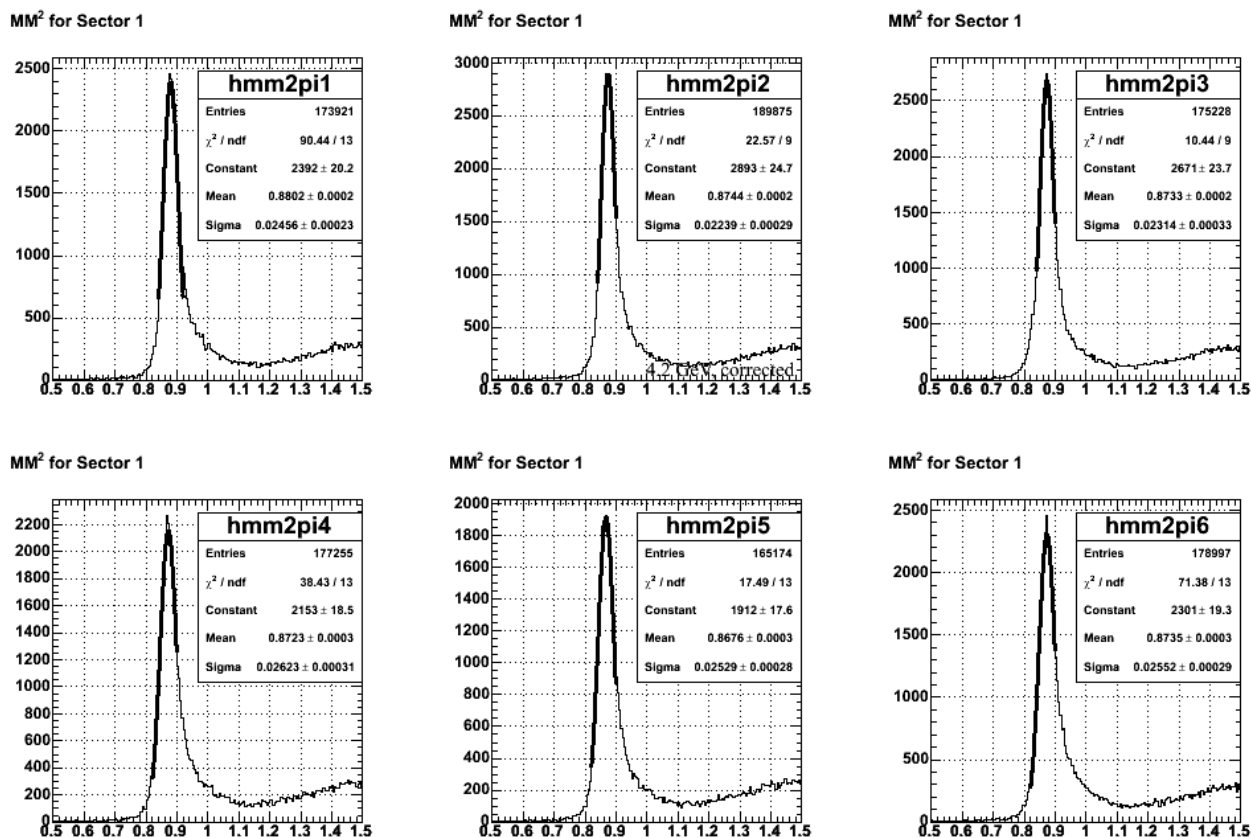

Fig 4. Uncorrected MM2 spectra to go along with Fig 3.

For the above set of parameters (i.e. for Figs 3-4) here is a table comparing the MM2 centroid and width of the $e\pi \rightarrow e\pi + (n)$ peak corrected and uncorrected. Same problem as before! The corrected results are worse than the uncorrected ones, though not as much worse as the W2 results.

Table 2.

Sector	corrected		uncorrected	
	centroid	width	centroid	width
1	0.8782	0.02708	0.8802	0.02456
2	0.8713	0.02404	0.8744	0.02239
3	0.8718	0.02581	0.8733	0.02314
4	0.8652	0.02747	0.8723	0.02623
5	0.8639	0.02552	0.8676	0.02529
6	0.8659	0.02643	0.8735	0.02552

The pcorr1 parameters from this latest run (7/30/05) are noticeably different from the current set so I save them below since I may try this set later.

Using those parameters from below later does make things better. I see improvements in centroid and width in some sectors and things get a little worse in others. The final comparison is below followed by the plots and files. The table below includes the latest results using the parameters at the end of this entry, plus the results from above.

Table 3.

Sector	W2 uncorrected		W2 corrected #1		W2 corrected #2		W2 corrected #3	
	centroid	width	centroid	width	centroid	width	centroid	width
1	0.8488	0.04771	0.7988	0.06696	0.8220	0.05663	0.8894	0.04873

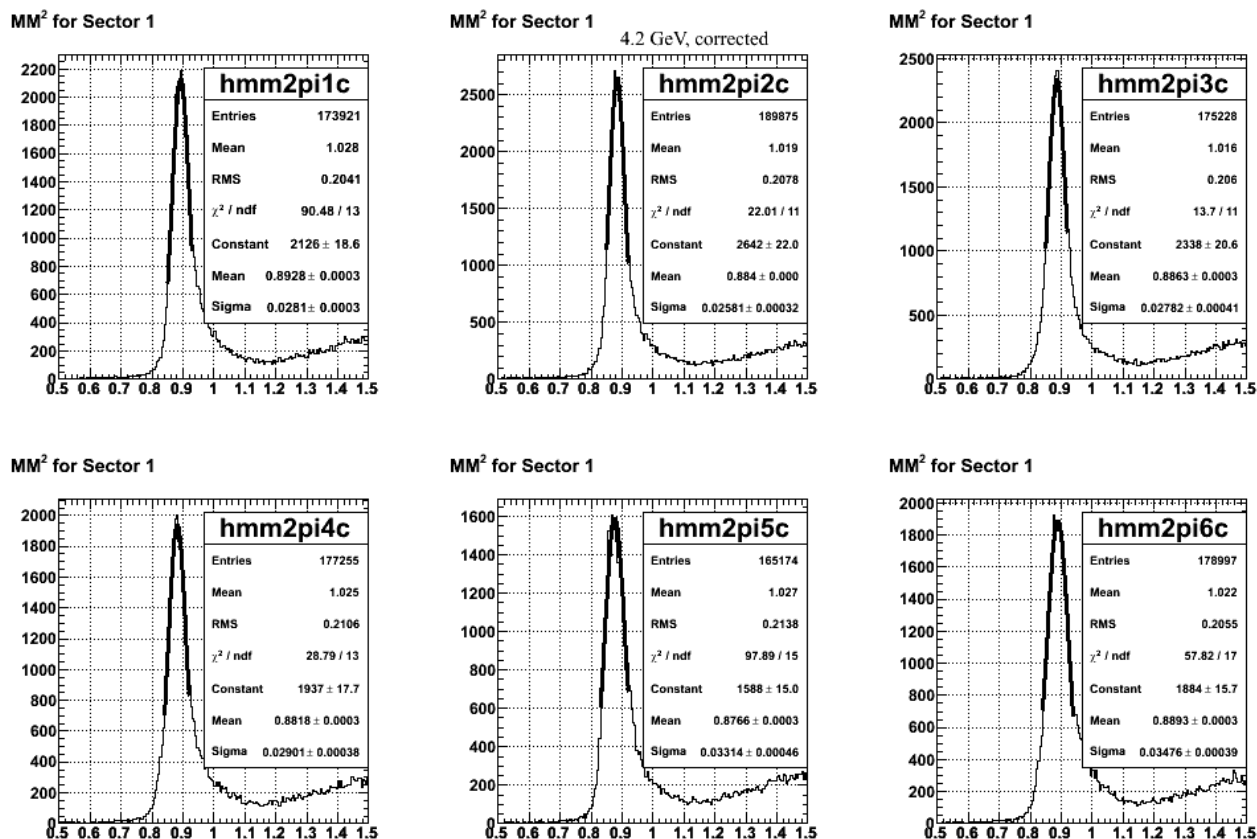

Fig 6. MM2 spectra sector-by-sector using the pccor1 parameters from the table below for 4.2 GeV

Click [here](#) to view the object (ROOT C++ macro for Fig 6) you uploaded.

The tabel below shows a comparison of the fits to MM2 spectra. The last two columns are the latest results using the pccor1 parameters at the end of this entry. The numbering corresponds to the parameter sets used in Table 3 above. The centroids and widths are better than the previous results with some improvement in spots and a little worse in others. Clearly better than the first set of parameters.

Table 4.

Sector	MM2 corrected #2		MM2 uncorrected		MM2 corrected #3	
	centroid	width	centroid	width	centroid	width

Jerry Gilfoyle's Enotebook page 77 - 4.2 GeV pcorr, VB method (gpg)

[Modified Tue Aug 2 21:20:28 2005 (GMT) gpg]

Below are the results for the 4.2 GeV, electron momentum corrections using the VB method. The alpha ratio for 4.2 GeV is shown below. The small number of counts is a surprise. It supposedly is due to the drop in the elastic cross section.

Denominator for alpha correction

2005-08-01 21:14:58

Fig 1. Alpha ratio for 4.2 GeV. The small number of counts is a surprise. It supposedly is due to the drop in the elastic cross section.

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

The plots below show the results of applying the VB method to correcting the electron momentum. The effect is small, but positive as shown in the table below.

Sector	Uncorrected		Corrected	
	centroid	width	centroid	width
1	0.8704	0.04080	0.8745	0.03416
2	0.8265	0.03718	0.8532	0.03530
3	0.8835	0.03660	0.8808	0.03370
4	0.8636	0.03211	0.8735	0.03046
5	0.8631	0.03413	0.8730	0.03079
6	0.8790	0.03068	0.8780	0.03093
ave	0.8644	0.03525	0.8722	0.03256

```

Denominator for alpha correction

Fig 5. Alpha 2D histogram for most recent set of analysis cuts. Here I opened up the good_W_cut because in one sector(2, I think), the uncorrected proton peak was being cut out at the low MM2 side because the W cut was too high.

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

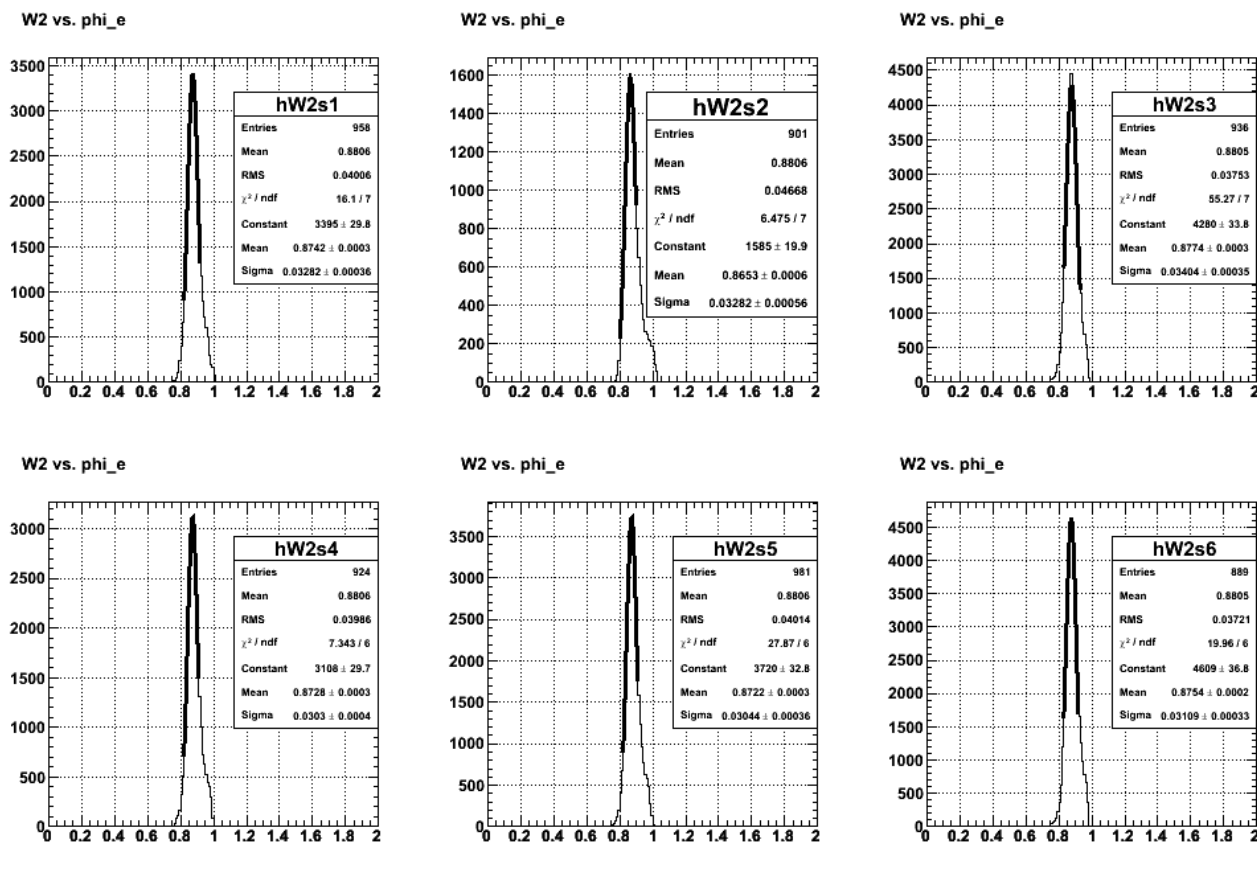

Fig 6. Fits to W^2 spectra sector by sector for 4.2 GeV using VB momentum correction with latest set of parameters after opening up the W cut.

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

Fig 7. Comparison of W^2 vs. ϕ_e without VB electron momentum corrections (left panel) and with them (right panel).

Click [here](#) to view the object (ROOT C++ macro for Fig 7) you uploaded.

Final comparison table with 'corrected 1' from previous table in this entry and 'corrected 2' from latest VB parameters

Uncorrected Corrected 1 Corrected 2

Jerry Gilfoyle's Enotebook page 78 - RB 4.2 GeV momentum correction results (gpg)

[Modified Thu Aug 11 21:27:48 2005 (GMT) gpg]

Below are Rusty's results for his momentum correction scheme.

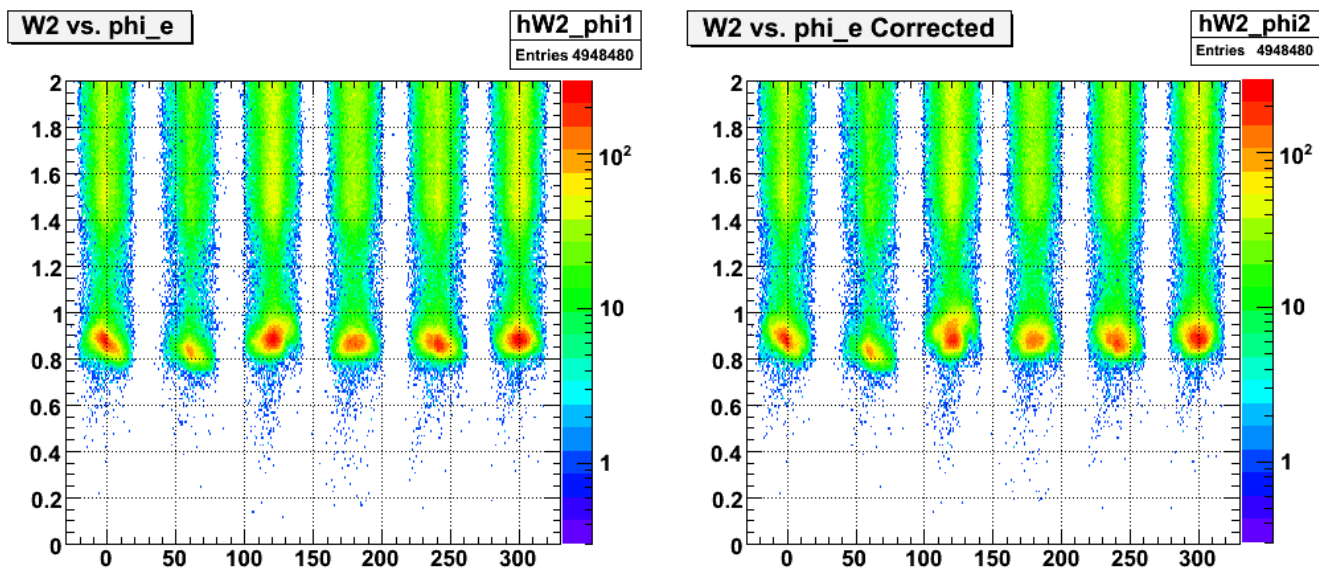

Fig 1. Comparison of W2 before and after applying momentum corrections for 4.2 GeV

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

Sector	Uncorrected		Corrected	
	Centroid	Width	Centroid	Width
1	0.8706	0.04199	0.8858	0.04106
2	0.8278	0.03844	0.8280	0.03836
3	0.8859	0.03870	0.8956	0.04502
4	0.8644	0.03500	0.8821	0.03800
5	0.8651	0.03570	0.8822	0.04940
6	0.8798	0.03160	0.8914	0.03831
Average	0.8656	0.03691	0.8775	0.04169

Rusty's results are not as good as the ones I got. He noticeably improved the centroid, but the width is about 12% worse.

Jerry Gilfoyle's Enotebook page 79 - Some tests of kinematic cuts (gpg)

[Modified Fri Sep 2 21:50:47 2005 (GMT) gpg]

Below is a table of the effect of different counts on the number of electron singles using /pscr1/gilfoyle/data/clas_024035.a01.b00.root

all cuts on	5346
efid off	7986
deuteron tgt off	18131
egyan threshold off	23092
EC fiducial off	24371
EC track coordinates off	25197
minimum photoelectron off	37977
all cuts off	37977

Fig 1. Comparison of electron acceptance with 4.2 GeV efid's off (left panel) and on (right panel). The missing counts at forward angles of sector 2 should be investigated.

2005-09-01 22:59:86

Fig 2. Same as figure 1 with most of the 4.2 GeV data.

Click [here](#) to view the object (ROOT C++ macro for Fig 2.) you uploaded.

The lack of counts at forward angles in Fig 2 for sector 2 is due to a lack of counts at high momenta in this sector. The plots of the edge positions (see link below) shows that at higher momenta there are simply not enough counts to adequately determine the position of the edge so we cut off the electron fiducials at an electron momentum of 2.2 GeV/c. These are higher momentum tracks because these are inbending electrons, the higher momentum tracks are 'stiffer' and bend less, so they can get to more forward angles before the tracks get bent down the hole.

Click [here](#) to view the object (Plots showing the degradation of the edges at higher electron momentum) you uploaded.

Jerry Gilfoyle's Enotebook page 80 - Investigating MM2 cut to identify neutrons (gpg)

[Modified Fri Sep 2 03:20:13 2005 (GMT) gpg]

The plot below shows a comparison of $N+$ vs. p_m for events with the neutron identified using $0.84 < MM2 < 0.92$ (left panel) and projecting $N+$ from a 2D spectrum of $MM2$ vs. p_m generated using $\sin(\phi)$ weighting (right panel). The two wildly disagree.

Fig 1. Comparison of $N+$ vs. p_m from usual method (left panel) and projecting $N+$ from a 2D spectrum of $MM2$ vs. p_m generated using $\sin(\phi)$ weighting.

Jerry Gilfoyle's Enotebook page 81 - E1 response to reversed torus current (gpg)

[Modified Mon Sep 5 16:06:15 2005 (GMT) gpg]

Below is a link to a section of Raffaella DeVita's(?) analysis note on the E1 data taken with reversed torus polarity.

Click [here](#) to view the object (section of E1 analysis note on reversed field data) you uploaded.

Jerry Gilfoyle's Enotebook page 82 - 4.2 GeV spectra (gpg)

[Modified Fri Sep 9 02:35:11 2005 (GMT) gpg]

Plots below show some investigations of the 4.2 GeV data. ALTP is essentially zero here so this is an attempt to see if there is anything salvagable in these data. The only cuts in Figure 1 are for epn_events, deuteron target, and minimum photoelectrons.

Fig 1. Unweighted spectra with all the cuts off except epn.

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

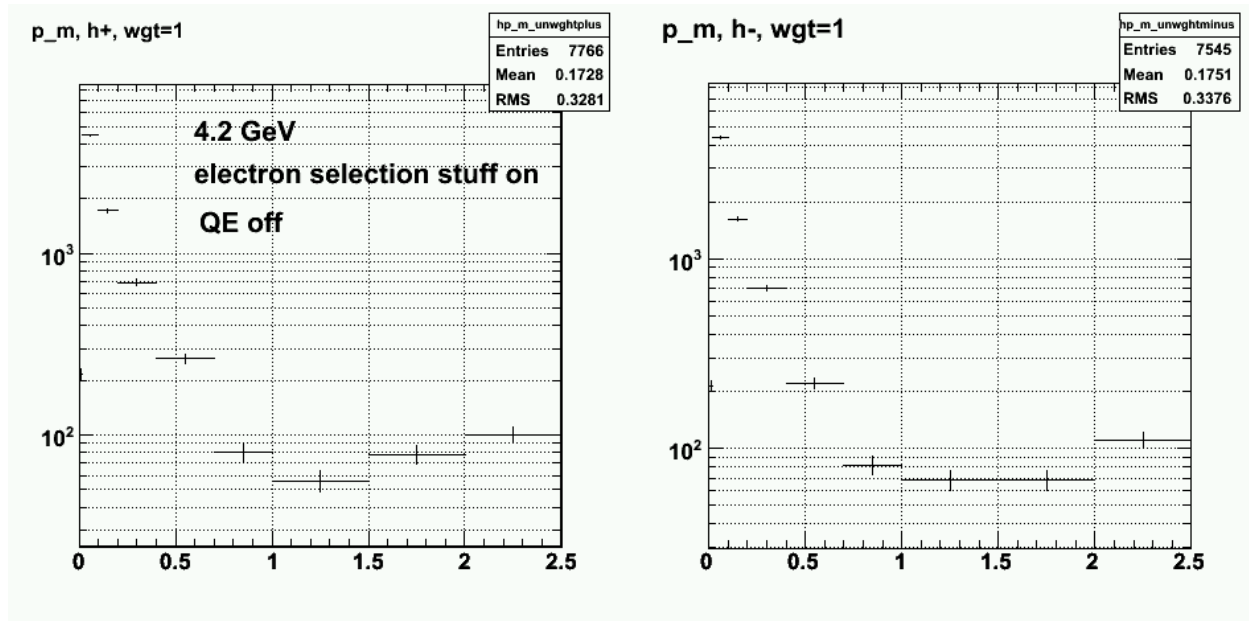

Fig 2. Unweighted spectra with all the cuts off except epn and electron selection stuff.

Click [here](#) to view the object (ROOT C++ macro for Fig 2) you uploaded.

Fig 3 ALTp for cuts in Fig 2.

Jerry Gilfoyle's Enotebook page 83 - ALTp from fitting at 4.2 GeV (gpg)

[Modified Thu Sep 15 23:07:06 2005 (GMT) gpg]

A comparison of results extracting ALTp using the method versus fitting the helicity asymmetry. There is obviously something wildly wrong.

2005-09-11 22:45:36

Fig 1.

Click [here](#) to view the object (ROOT C++ macro named 4.2nALTpfits.C for Fig 1.) you uploaded.

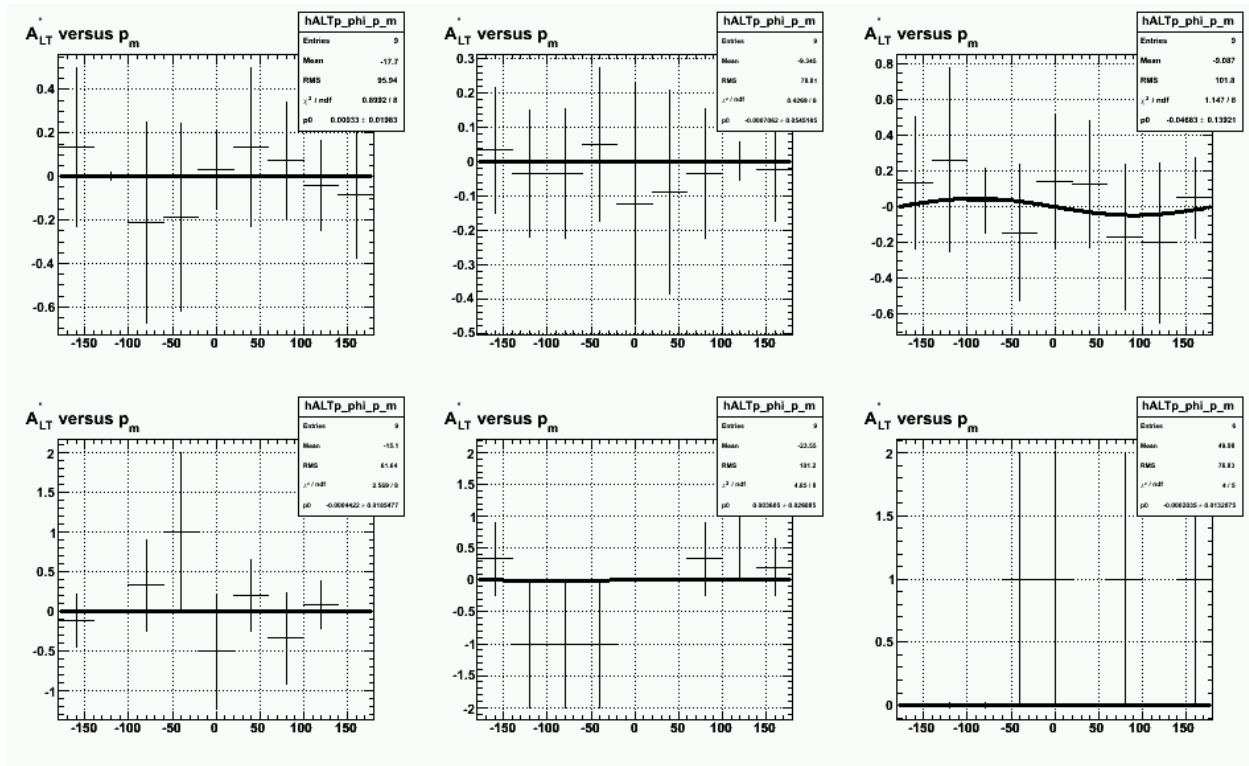

Fig 2. Fitting helicity asymmetry results

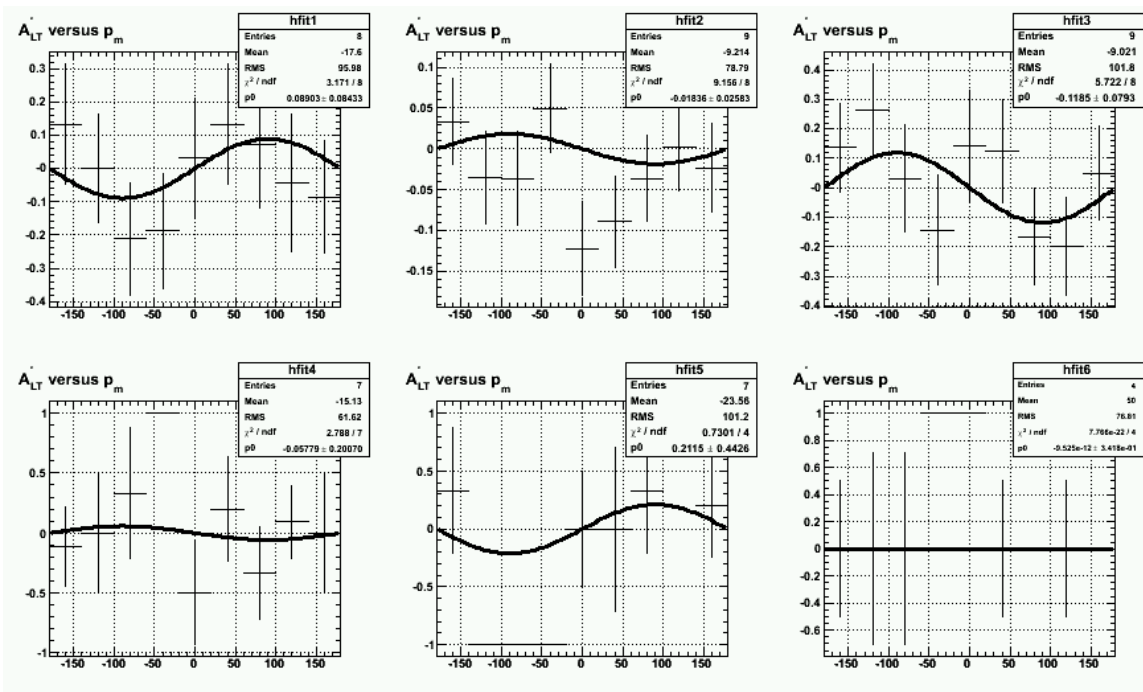

Fig 3. Fixed the uncertainties and get the above results. There is a problem in pbin=6 because there are simply so counts in some of the phi_pq bins and i don't know how to handle the uncertainty.

Click [here](#) to view the object (ROOT C++ macro for making Fig 3) you uploaded.

Click [here](#) to view the object (ROOT macro for generating Fig 3) you uploaded.

Fig 4. Comparison of ALTP from and helicity asymmetry fits. Compare this with Fig 1. Things look much better until I run out of counts at large p_m .

Click [here](#) to view the object (ROOT C++ macro for Fig 4) you uploaded.

Fig 5. Compare AL_Tp from 3D hist with MM2 axis with results from 2D hist and used above.

Fig 6. AL_Tp generated from fits to first p_m bin from 2D phi_{pq} vs. p_m histogram

Helicity asymmetry for p_m bin 1 generated from 2D ϕ_{pq} vs p_m histogram extracted from 3D MM2 vs. ϕ_{pq} vs. p_m

Click [here](#) to view the object (ROOT C++ macro for extracting ALTp from the 3D MM2 vs. ϕ_{pq} vs. p_m histogram for the 4.2 GeV data) you uploaded.

Click [here](#) to view the object (ROOT C++ macro for extracting ALTp vs. p_m from 2D ϕ_{pq} vs p_m 2D histogram using equal bin sizes to match the extraction of ALTp from the 3D histogram mentioned in the previous entry for 4.2 GeV.) you uploaded.

Click [here](#) to view the object (Same as previous ROOT C++ macro except it uses the 2D ϕ_{pq} vs. p_m histogram with the variable bin sizes in p_m .) you uploaded.

Click [here](#) to view the object (ROOT histogram file with the histograms used to test the ALTp algorithms in the previous 3 items.) you uploaded.

Jerry Gilfoyle's Enotebook page 84 - 4.2 GeV sector 6 pfid (gpg)

[Modified Wed Sep 28 16:23:09 2005 (GMT) gpg]

Sector 6 round 3.

Tue Sep 27 21:36:28 2005

Fig 1. 3gen fits for round 3. see .dat file below.

Jerry Gilfoyle's Enotebook page 85 - pfid tests (gpg)

[Modified Tue Oct 18 13:58:25 2005 (GMT) gpg]

The first look at the effect of the 4.2 GeV pfid is disturbing as shown below. The events outside the fiducials are eliminated, but it also looks like 80% of the events in the fiducial region are getting punted. The only difference between the left and right panels in Fig 1 is turning the proton fiducials on. A mystery?!!

Fig 1. Comparison showing effect of no 4.2 GeV pfid cut (left panel) and with proton fiducial cuts on (right panel) for all momenta.

After fixing numerous programming errors, I get the following plot which looks much better. What is worrisome now is why am i losing counts in the middle of the fiducial region? Is this because of the implicit momentum limits in the proton fiducial cuts? See fig 3.

Fig 2. Comparison after fixing programming errors showing effect of no 4.2 GeV pfid cut (left panel) and with proton fiducial cuts on (right panel) for all momenta.

Click [here](#) to view the object (ROOT C++ macro for Fig 2.) you uploaded.

Do the same analysis, but restrict the range of the data with pfid's off to $0.1 < p_{\text{proton}} < 2.1$ to reproduce the implicit momentum cut on p_p in the pfid function. That appears to improve the agreement significantly. Namely, there should be little or no difference between the two acceptances in Figure 3 in the fiducial region. The proton fiducial cuts should just throw out the events outside this fiducial range. There still appears to be some small differences. Let me check the exact proton momentum range. See the results in Figure 4.

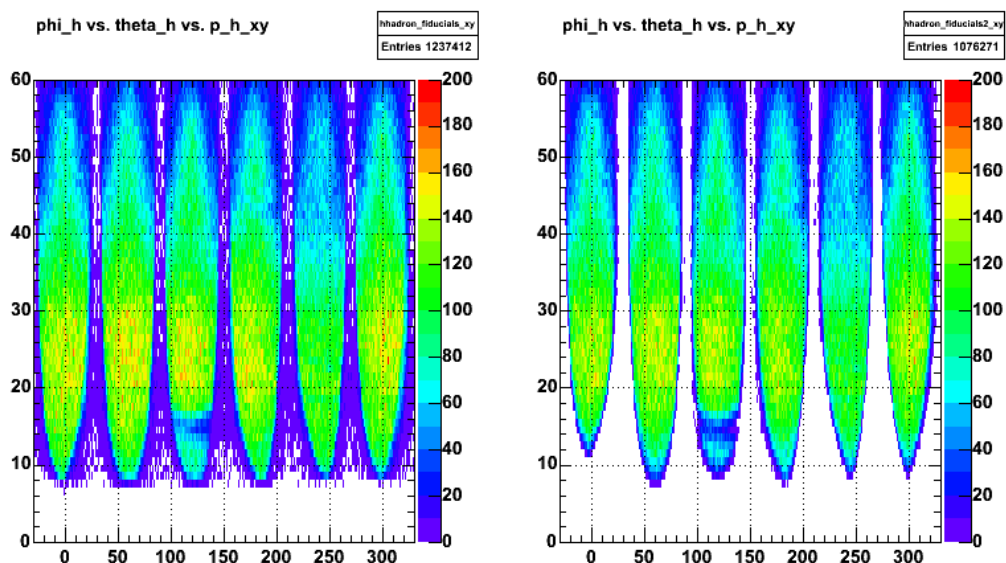

Fig 3. Comparison of effect on acceptance with proton fiducials off (left) and on (right).

Click [here](#) to view the object (ROOT C++ macro for Fig 3.) you uploaded.

Fig 4. Same as Figure 3, but I fixed a small error in the left-hand, no-pfids acceptance. In Figure 3 I required $0.1 \text{ GeV}/c < p_p < 2.1 \text{ GeV}/c$ to reproduce the limits on p_p in the pfid function. Those limits should have been $0.1 \text{ GeV}/c < p_p < 2.0 \text{ GeV}/c$.

Click [here](#) to view the object (ROOT C++ macro for Figure 4.) you uploaded.

Click [here](#) to view the object (ROOT histogram file for Figure 4.) you uploaded.

Click [here](#) to view the object (C++ code used in ROOT for analysis for Figure 4) you uploaded.

Fig 5. Same as Fig 4, but we fixed the ultra-small uncertainties on some of the points in the t_0 fit for sector 1. This caused a significant change in the fit to the t_0 as a function of p_p which eliminated this high θ_p cutoff that is visible in Fig 4.

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

Click [here](#) to view the object (ROOT histogram file used for Fig 5.) you uploaded.

Click [here](#) to view the object (Slightly fancier version of the ROOT C++ macro for the last figure.) you uploaded.

Fig 6. I am seeing lots (30%) of the events thrown out when I turn on the pfids. Looking at the excluded events shown above there is clearly a problem. Some events in the good fiducial region are getting excluded by the function.

Mon Oct 17 22:12:27 2005

Fig 6. Examining one sector and proton momentum fiducial cut in detail.

The results for the pfid tests actually look ok. The crappy looking stuff in Fig 5 is due to the use of a large p_p range to project out the data onto the ϕ_p - θ_p plane. At low p_p , the minimum angle increases. If you project out data from a low p_p to a 'high' p_p range it looks like the fiducial region of the detector is getting filled in. When you look at narrow p_p bins separately there is no problem. See Fig 7. below.

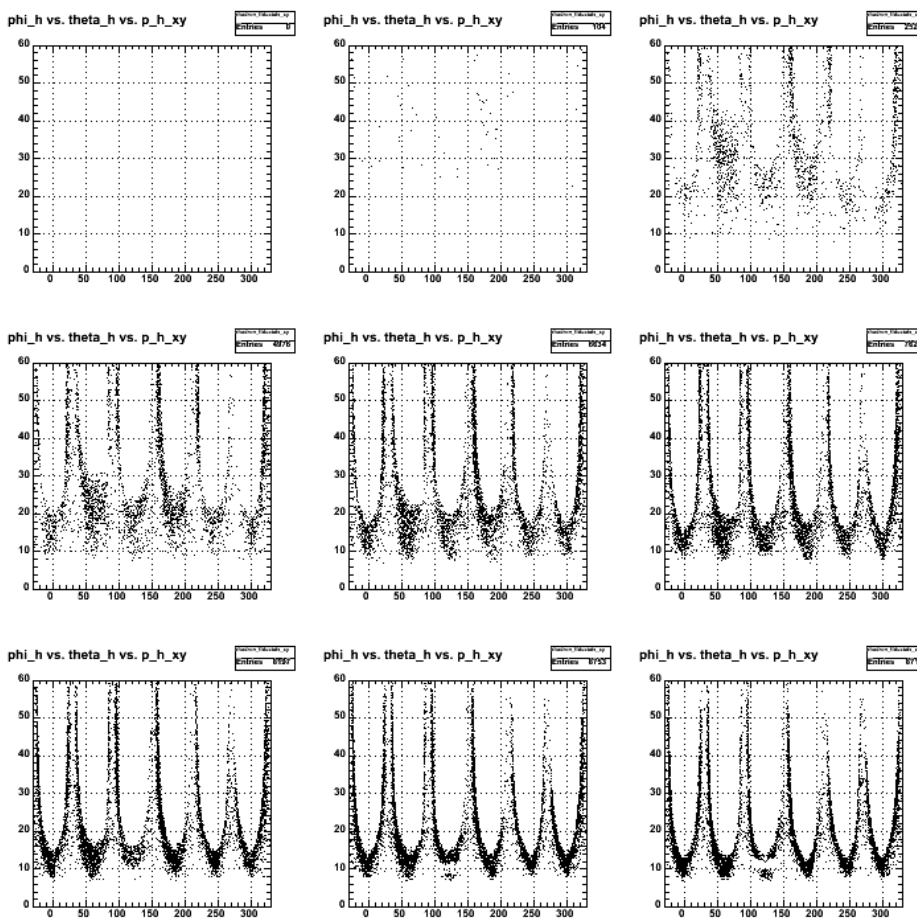

Fig 7. Plot of excluded protons for $p_p = 0.1-0.9$.

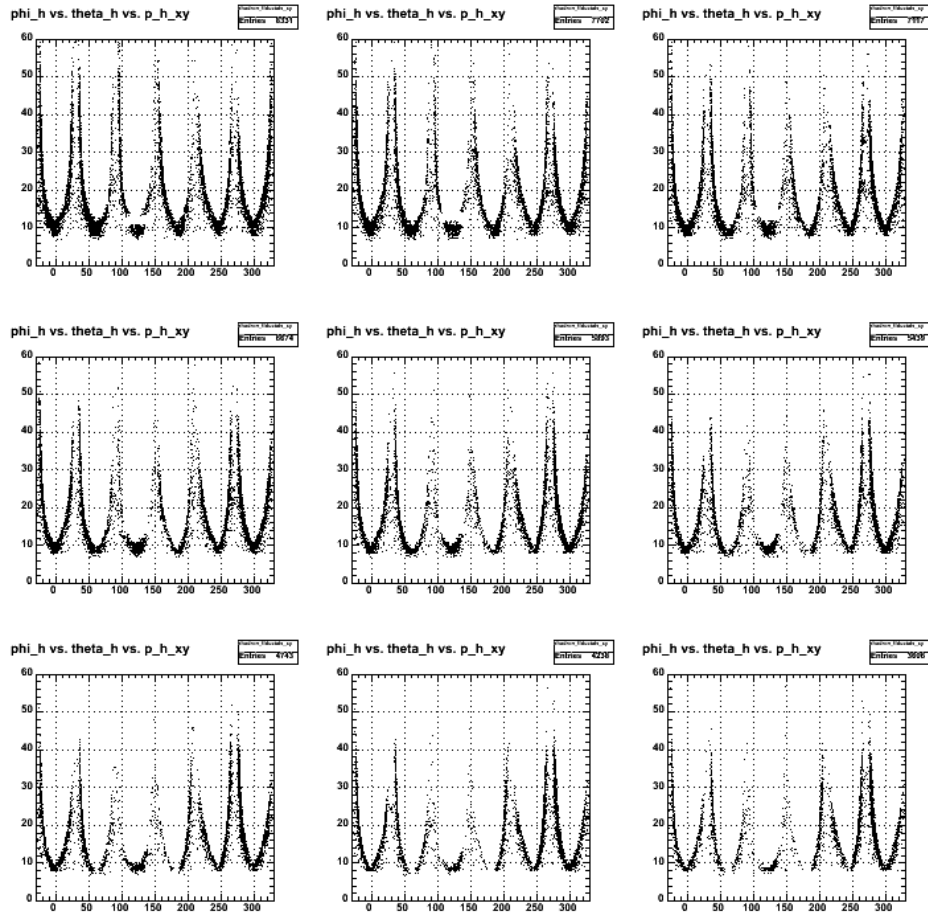

Fig 8. Plot of excluded protons for $p_p = 1.0 - 1.8 \text{ GeV}/c$

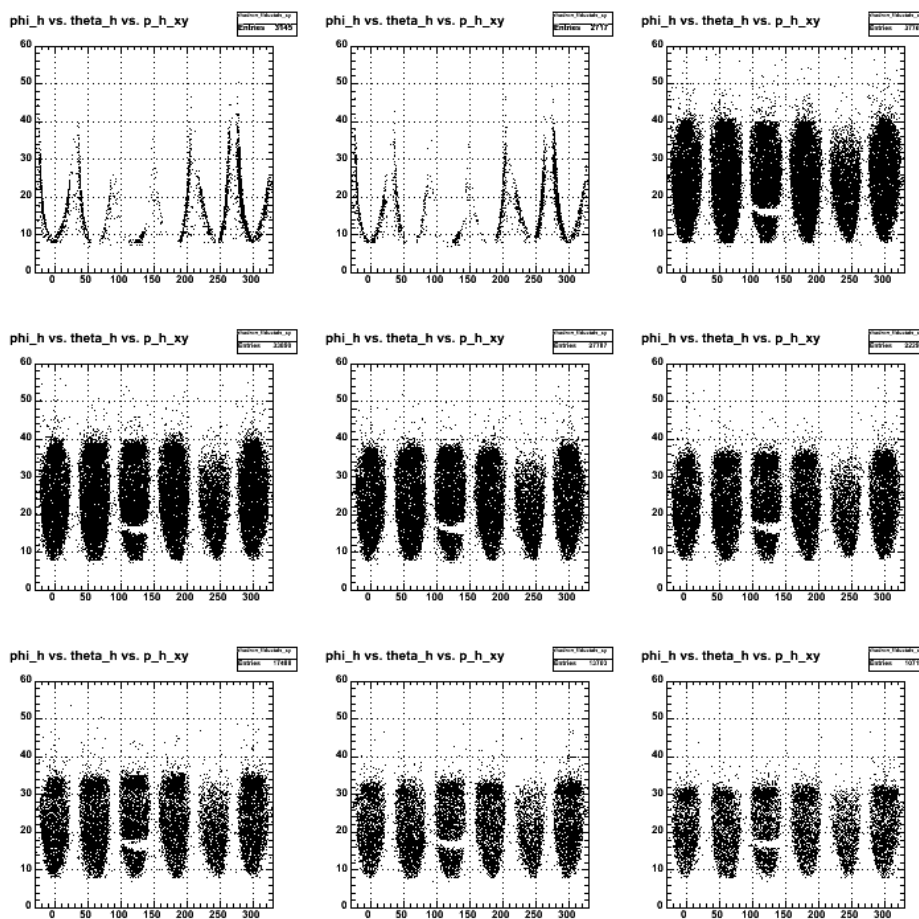

Fig 9. Plot of excluded protons for $p_p = 1.9-2.7$ GeV/c

Fig 9. Momentum distribution of protons excluded by the proton fiducial cut showing the cutoff at $p_p=2.4$ GeV/c. The limit was extended from 2.0->2.4 GeV/c just to see the effect which looks ok. See next plot.

Fig 10. Extended the range of the proton fiducial cuts from 2.0->2.4 GeV/c to see if it would look ok and it does. The limit of 2.0 GeV/c was driven by the statistics of the first generation fits.

Jerry Gilfoyle's Enotebook page 86 - fitting missing mass spectra (gpg)

[Modified Sun Oct 16 20:28:49 2005 (GMT) gpg]

The plots below show first results from fitting the missing mass spectra with an eye to testing the effect of fitting the missing mass to get the neutron counts that go into the helicity asymmetry.

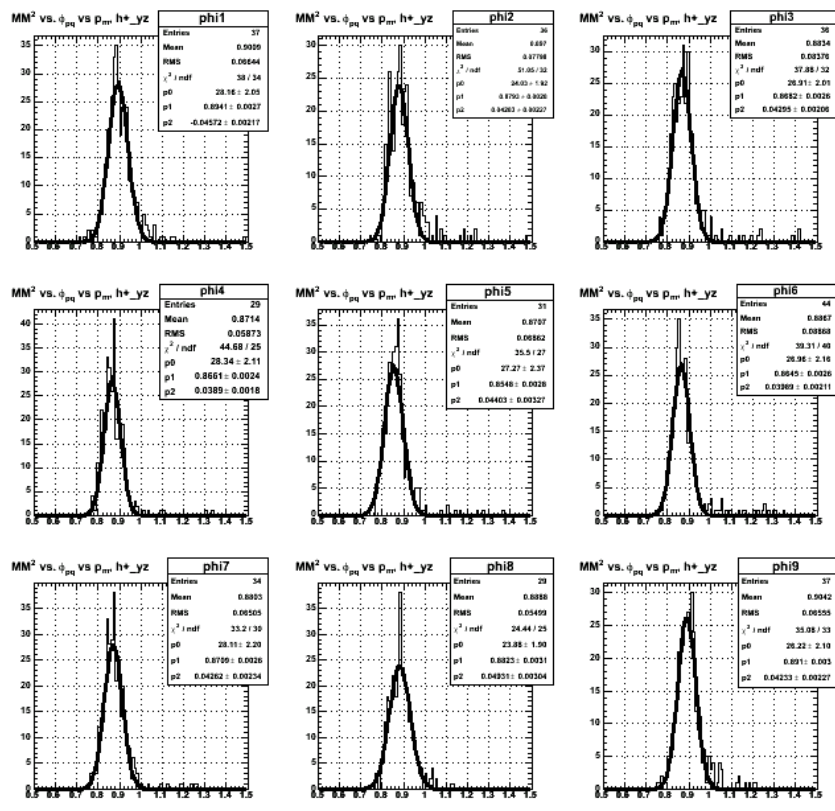

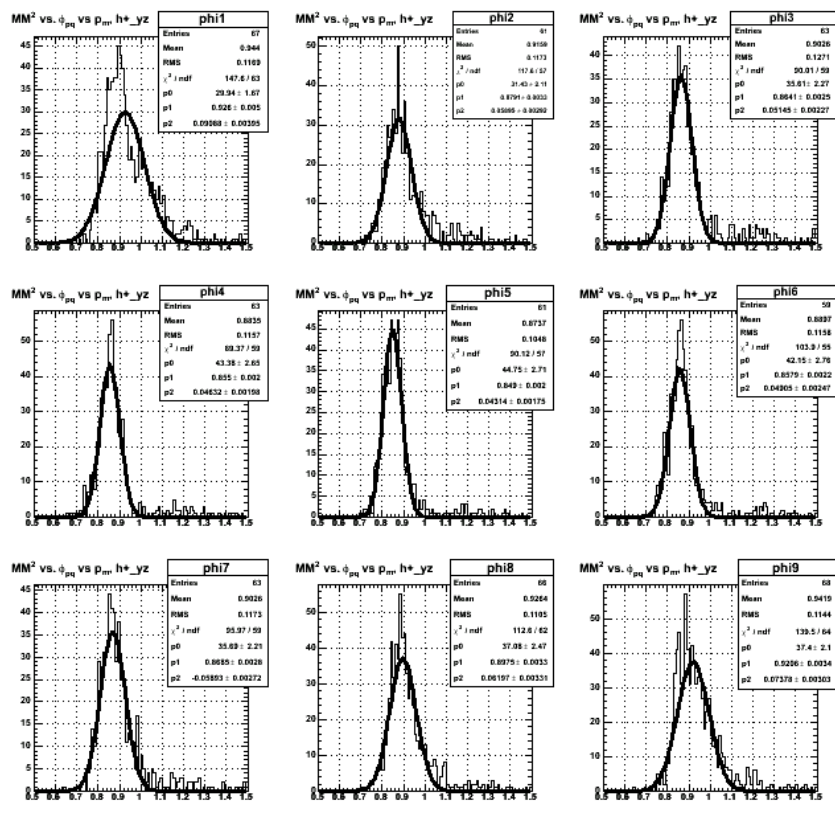

Fig 1. Fits for p_m bin = 1

Fig 2. Fits for p_m bin=2.

Click [here](#) to view the object (PS file for Fig 1.) you uploaded.

Click [here](#) to view the object (ROOT C++ macro for Fig 2) you uploaded.

I've completed writing a first version of the code for doing the fitting of the helicity asymmetry. The plot below shows the results for ALTP as a function of p_m for 4.2 GeV. The plot shows ALTP derived from a simple integral of the spectrum below $MM_2=1.0$ GeV. When I did the same analysis using a gaussian fit, the results were ugly because there are so few counts at large p_m . The links after the figure include copies of the ROOT code, PostScript files showing the fits, and a macro for the figure itself.

4.23 GeV, normal polarity

Click [here](#) to view the object (ROOT C++ macro file mm2fit5.C which uses a simple integral to get the helicity asymmetry.) you uploaded.

Click [here](#) to view the object (ROOT C++ macro file mm2fit4.C which uses a gaussian to get the helicity asymmetry. Does not work well when the number of counts is very small at large p_m .) you uploaded.

Click [here](#) to view the object (ROOT histogram file used with the codes above.) you uploaded.

4.23 GeV, normal polarity

2005-10-14 18:00:55

Fig 4. A_{LT} vs. p_m extracted with a gaussian fit. there are simply not enough counts at large p_m so the fits crap out. See the next link with the PostScript file containing the intermediate results.

Click [here](#) to view the object (PostScript file containing the intermediate fit results for Fig 4) you uploaded.

4.23 GeV, normal polarity

Jerry Gilfoyle's Enotebook page 87 - comparing ALTp methods for QE kinematics (gpg)

[Modified Wed Oct 26 21:58:00 2005 (GMT) gpg]

Generate the distributions and use the following code to extract ALTp.

```
TH1F *h1a = new TH1F("h1a","Sin(phi) weighted distribution for positive helicity",14,0.0,0.7);
TH1F *h2a = new TH1F("h2a","Sin(phi) weighted distribution for negative helicity",14,0.0,0.7);
h1a.Sumw2();
h2a.Sumw2();
h1a.Divide(hp_m_sin_phi_wghtplus, hp_m_unwghtplus);
h2a.Divide(hp_m_sin_phi_wghtminus, hp_m_unwghtminus);
TH1F *h12a = new TH1F("h12a","A_{LT}",14,0.0,0.7);
h12a.Sumw2();
h12a.Add(h1a,h2a,1.0,-0.9994);
h12a.Draw();
float pol=0.73;
TF1 f1("unity","1.00",0,10)
h12a->Divide(unity,0.73)
h12a->Draw();
```

2005-10-16 15:42:58

Click [here](#) to view the object (ROOT C++ macro for Fig 3) you uploaded.

2005-10-16 17:29:06

Fig 4. Comparison of the two methods for extracting ALTP after I included a lower limit on MM2 in mm2fit5.C to reproduce the cuts in eod5.C. The limits are bins 34-42.

To see if the fluctuations of the data in these plots are consistent with $ALTP=0.0$, I fit the data with a straight line. The result is shown below and the data (asymmetries and uncertainties) are consistent with zero.

2005-10-16 17:48:86

Fig 5. Checking the consistency of the asymmetries and the uncertainties.

Figures 6 and higher (below) are for quasielastic kinematics.

Fig 6. ALTp with all cuts on (efid, pfid) using the method.

Fig 6 should be compared to Fig 7 below, but there are some obvious problems. Fig 7 shows the results of the fits to the helicity asymmetry as a function of p_m .

Many of the missing momentum bins have few or no counts so the fits can't be made to the helicity asymmetry as a function of ϕ_{pq} . This is disappointing.

Fig 7. A_{LT}' with $efid$ and $pfid$ on derived from the fits to the helicity asymmetry as a function of p_m .

Turning on the momentum corrections has a very minor effect. The values for A_{LT}' move a bit, but much less than the error bars. See Fig 8 and the following table for a comparison.

Fig 8. Same as Figure 6 with momentum corrections turned on.

without momentum corrections

```

Jerry Gilfoyle's Enotebook page 90 - Learning to run gsim (gpg)

[Modified Tue Nov 1 23:53:10 2005 (GMT) gpg]

Here are some notes on learning to run gsim.

getting gsim running

see files in /home/gilfoyle/research/eod/gsim

sequence

1. generate input file of 4-vec using gsim1.nb (Mathematica).

2. generate BOS banks using

```
txt2part_e5_linux -ogsiminput.evt < gsim1.dat
```

to get input BOS banks for gsim.

3. start gsim_int using

```
source rungsim
```

4. once in gsim use the following to start

```
switch 1 2
dcut clas 2 0 10 10 0.015 0.015
trig 1
```

and then to see more events use

```
clr
dcut clas 2 0 10 10 0.015 0.015
trig 1
```

quit

5. run the results through recsis.

```
recsis -t recsis1.tcl -i gsimpg.evt.A00 -o test1.root -np
recsis -t recsis2.tcl -i gsimpg.evt.A00 -o test1.root -np
```

the above lines don't work. the runIndex is always set to zero so looking up stuff in caldb fails. use user_ana.

```
user_ana -t recsis_test.tcl -i clas_045613.A00 -o test1.root -np
user_ana -t recsis2.tcl -i gsimpg.evt.A00 -o test1.root -np
```

i don't understand yet what is the output of -o.

this step is where i may want to copy what jeff L. did for his analysis.

6. run a1c_ntup to create the ntuples.

7. and then convert them to root files.

```
h2root re5761.rzn
```

Jerry Gilfoyle's Enotebook page 91 - ALT and ATT in QE kinematics (gpg)

[Modified Thu Nov 3 21:38:54 2005 (GMT) gpg]

The plots below show ATT and ALT at 4.2 GeV in QE ($0.92 < W < 1.0$ GeV) kinematics.

2005-11-02 07:23:53

```

For quasielastic kinematics, ALTP goes to zero at $p_m=0$ because ALTP is (in PWIA) due solely to FSI. At $p_m = 0$ or $\theta_{pq}=0$, the struck proton is going straight out of the deuteron in the same direction as the incoming virtual photon. If it hit the neutron on the way out (i.e., a final-state interaction (FSI)), then it would be deflected away from $p_m=0$. Perhaps this no longer applies for delta kinematics because the proton can get to $p_m=0$ because the virtual photon and proton combine to form a delta within the deuteron which then decays. The emission of another particle can push the proton away from $p_m=0$ and then FSI could knock it back to $p_m=0$.

Jerry Gilfoyle's Enotebook page 94 - lost counts in 2.6r setting (gpg)

[Modified Wed Nov 9 04:01:00 2005 (GMT) gpg]

In re-analyzing some of the 2.6r data I found tons of extra counts in the latest analysis for ALTP. Comparing the old Q2 distribution with the latest one it's obvious why. Somehow I had lost about 80% of the data! Compare the number of counts at the peak of the Q2 distribution for Fig 1-2. Did I screw up and not analyze all the data? Mysteries abound!

h1

Fig 1. Old Q2 distribution for 2.6r from entry ??.

Jerry Gilfoyle's Enotebook page 97 - weird results for ALTp at 4.2 GeV (gpg)

[Modified Wed Nov 16 04:08:34 2005 (GMT) gpg]

Weird science??? The weirdness is that there are asymmetries that are larger than one. two effects contribute to this problem. First, the asymmetry in a particular p_m bin is calculated as

$$ALTp = \langle \sin(\phi_{pq+}) \rangle - \langle \sin(\phi_{pq-}) \rangle \quad (1)$$

where

$$\langle \sin(\phi_{pq}) \rangle = \text{Sum}(\sin(\phi_{pq}_i))/N \quad (2)$$

where N is the total number of positive or negative helicity events. The denominator is the $\sin(\phi_{pq})$ -weighted sum for a particular p_m bin. Consider an extreme case where there is a single event in the positive helicity bin with $\sin(\phi_{pq})=+1$ ($\phi_{pq}=90$ deg) and a single event in the negative helicity bin with $\sin(\phi_{pq})=-1$ ($\phi_{pq}=-90$ deg). This will give you an ALTp close to 2. This 'problem' disappears if you increase the bin size so that you get at least a few events. Also, the uncertainty on these pathological events is very large. When I look at the histogram for plus and minus helicity, the entries are always less than one even when there are few events. See Figure 3.

This effect can be compounded because we divide out the polarization of the beam at the end which is usually about 0.73. This can push this statistical pathologies over 1.0.

The other weird problem is that there are points at large p_m in [Fig 1 in entry 96](#) with very small ALTp (close to zero) with an uncertainty close to zero. This again is a product of small statistics. Suppose there is one event in a bin with $\phi_{pq} = 1$ deg. Then the weighted sum for that bin is $\sin(\phi_{pq}) = \sin(1 \text{ deg}) = 0.017 \pm 0.017$. You obtain a small weighted sum with a small uncertainty. The actual results that lead to the anomalous point for $p_m=0.55-0.60$ GeV/c are below.

$$\sin\phi_{\text{weightplus}}=0.00071305 \text{ for } p_m = 0.55-0.6 \text{ GeV/c}$$

Here $\phi_{pq}=0.41$ deg and the uncertainty will be equal to the same $\sin\phi_{\text{weightplus}}$.

Fig 3. results for 4.2 GeV

Jerry Gilfoyle's Enotebook page 98 - Compiling JML code in EXCLURAD (gpg)

[Modified Tue Nov 22 18:20:43 2005 (GMT) gpg]

Changes necessary to compile and link Jean-Marc Laget's code in EXCLURAD.

1. Had to add some stuff to my .cshrc file like defining the OSNAME as Linux and setting the CERNLIB environment variables to the correct values.
2. Had to explicitly declare the array pthfi(26) as real*4 because EXCLURAD has implicit real*8 defined in the main routine.
3. Put JML's object module in a separate directory so it wouldn't get deleted when I occasionally remove all the object modules. Added

```
OBJ += ../save/gdpm_mc.o
```

to the Makefile to pick up JML's routines.

4. Removed

```
-fno-second-underscore
```

from the fortran compiling options. This fixed the following link error.

```
exclurad.o(.text+0x5210): In function `phy_model_':  
/home/gilfoyle/eod/exclurad/addjmlp/exclurad.f:1087: undefined reference to `gdpm_mc_'  
collect2: ld returned 1 exit status  
make: *** [exclurad_wvojml_p_Linux] Error 1
```

The old code in the Makefile was

```
F77OPT += -ffixed-line-length-none -fno-second-underscore -DLinux
```

which was replaced with

```
F77OPT += -ffixed-line-length-none -DLinux
```

Jerry Gilfoyle's Enotebook page 99 - The lost events mystery, part deux and new 4.2 GeV efids (gpg)

[Modified Thu Dec 22 15:21:33 2005 (GMT) gpg]

There is a large discrepancy in the number of epn events when the efids and pfids are turned on. I lose about 80% of the events. I have seen this before and thought it was because of the implicit momentum cuts that are in the pfids, but this now looks like that implicit momentum cuts may be costing us real events. See previous discussion in entry [85](#). The first plot below shows the inputs to ALTp. Note the large difference in the number of counts when the efids and pfids are turned on.

Do a simple test where I just count the number of ep events with the following conditions set, it appears there is no great problem. I lose about half (40%) of the events when I turn the electron fiducials on and another 16% when the proton fiducials are turned on.

```
for ep2_count efids on, pfids off 10846 +/- 104 16%
ep_count efids on, pfids on 9343 +/- 97
```

```
for ep2_count efids on, pfids off 1106 +/- 33 17%
ep_count efids on, pfids on 949 +/- 31
```

```
for ep2_count efids off, pfids off 17161 +/- 131 84%
ep_count efids on, pfids on 9343 +/- 97
```

However, when I look at epn coincidences I see the effect again.

```
for epn2_counts efids off, pfids off 1851
epn_counts efids on, pfids on 229
```

```
for epn2_counts efids off, pfids on 1672
epn_counts efids on, pfids on 229
```

```
for epn2_counts efids on, pfids off 374
epn_counts efids on, pfids on 229
```

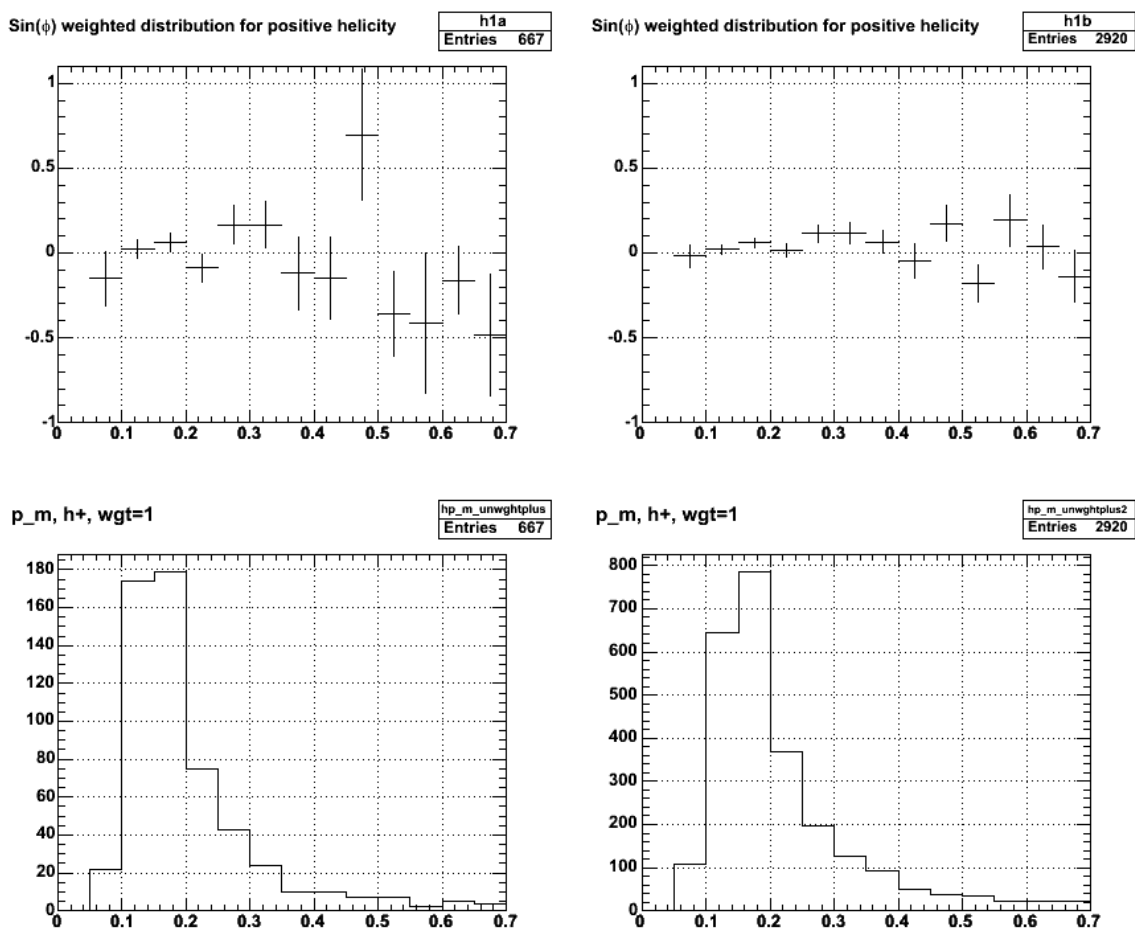

Figure 1. Comparison of inputs to ALTp for 4.2 GeV with efids and pfids on (left panels) and off (right panels). This is for delta kinematics. Compare with Fig 11 to see the happy effect of the new efids.

Continue to study the effect. Could this be a result of the implicit momentum cut in the electron fiducial cut?

```
for epn2_counts efids off, pfids off 126 0.8 < p_e < 2.4
epn_counts efids on, pfids on 229
```

The plot below shows epn events that are excluded by the electron fiducial cuts. The implicit momentum cut is at $p_e=2.8$ GeV except for secto2 where it is $p_e=2.1$ GeV. The problem seems to track with the implicit momentum cut. Things look ok in the range and then I start to see lots of events in the fiducial region outside the implicit momentum cut.

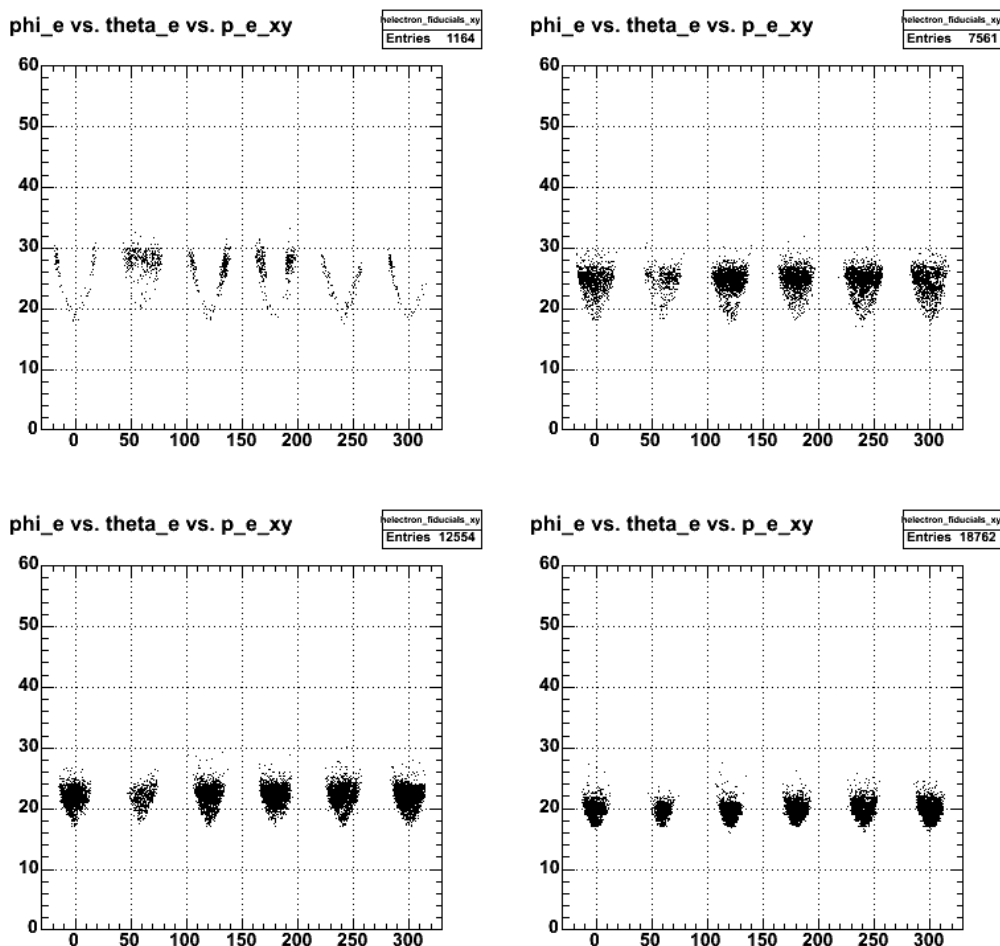

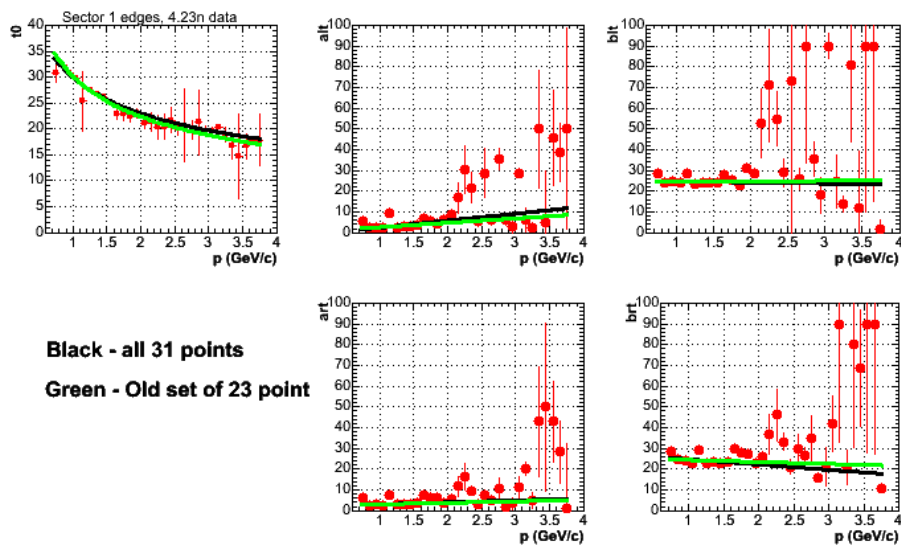

Fig 2. These are epn events that are excluded by the electron fiducial cuts.

After using the linear fit to the electron fiducial momentum dependence described in the plot above, we re-examine the spectra that alerted me to the problem (see Fig 1). Fig 10 below shows the comparison. The electron and proton fiducials are cutting out about half the data which is more typical and much better than the 80% loss in Fig 1. To make this comparison with Fig 1 more valid I have to use the same kinematics (delta, I think).

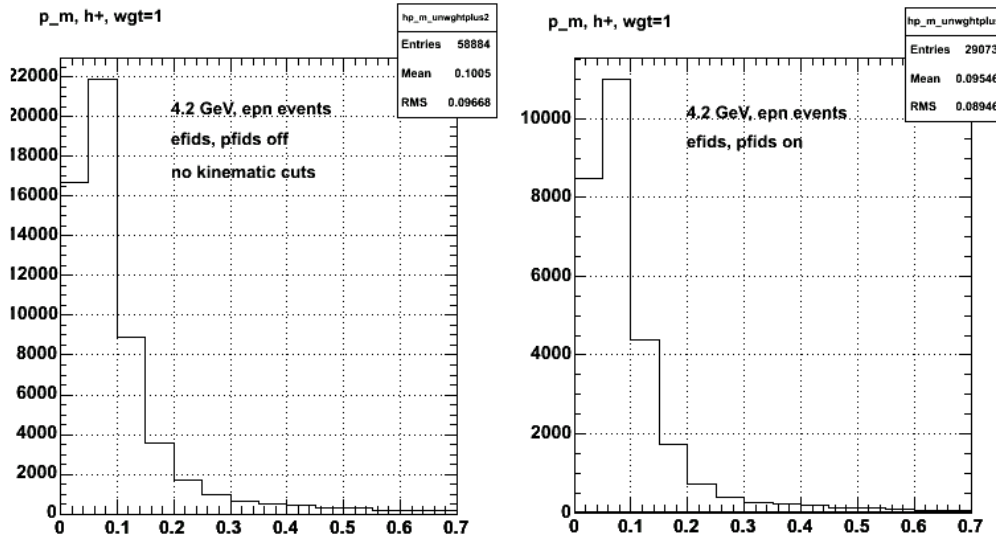

Fig 10. Comparison of unweighted missing momentum spectra for epn events with efids and pfids off (left panel) and on (right panel). There are no restrictions on the kinematics for these plots. Compare with Fig 1.

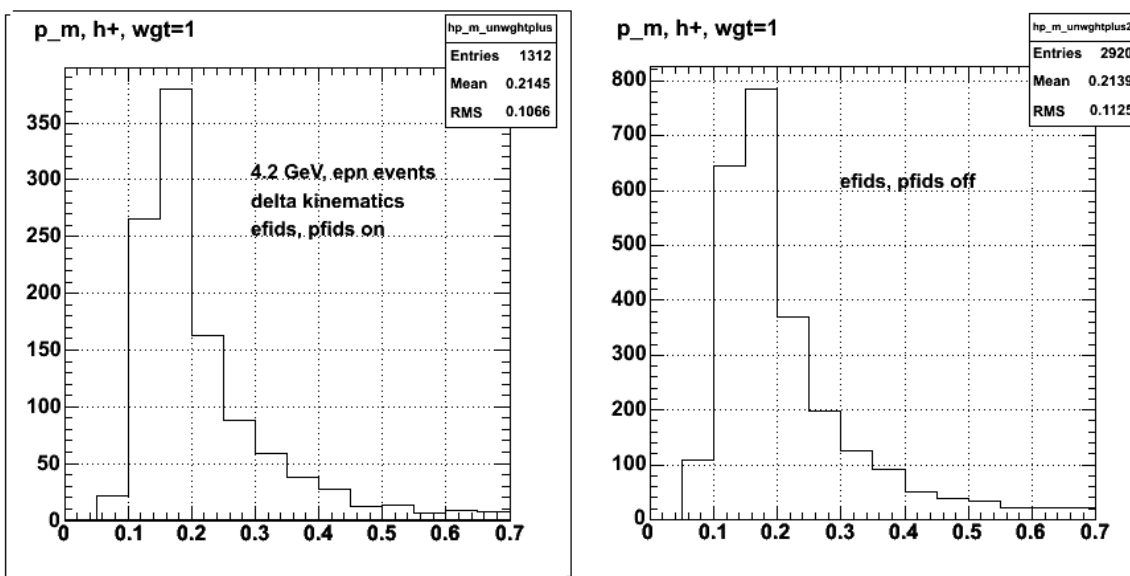

Fig 11. Comparison of inputs to ALTP for 4.2 GeV with efids and pfids on (left panels) and off (right panels) for new efids. This is for delta kinematics. Compare with Fig 1.

Looking at the Fig 1, the linear (pol1) fit for art actually goes negative at low hadron momentum. The actual fit results do not. This doesn't seem to be physically acceptable so I should use pol2 for this parameter even though going to pol2 has a limited improvement in the chisquare.

The pol1 fits look good enough for blt and brt.

Fig 1. 3gen fits for sector 1, 2.6r with pol1 in alt, blt, art, brt; pol2 in t1U and t1L; pol0 for phimid; and power fit for t0.

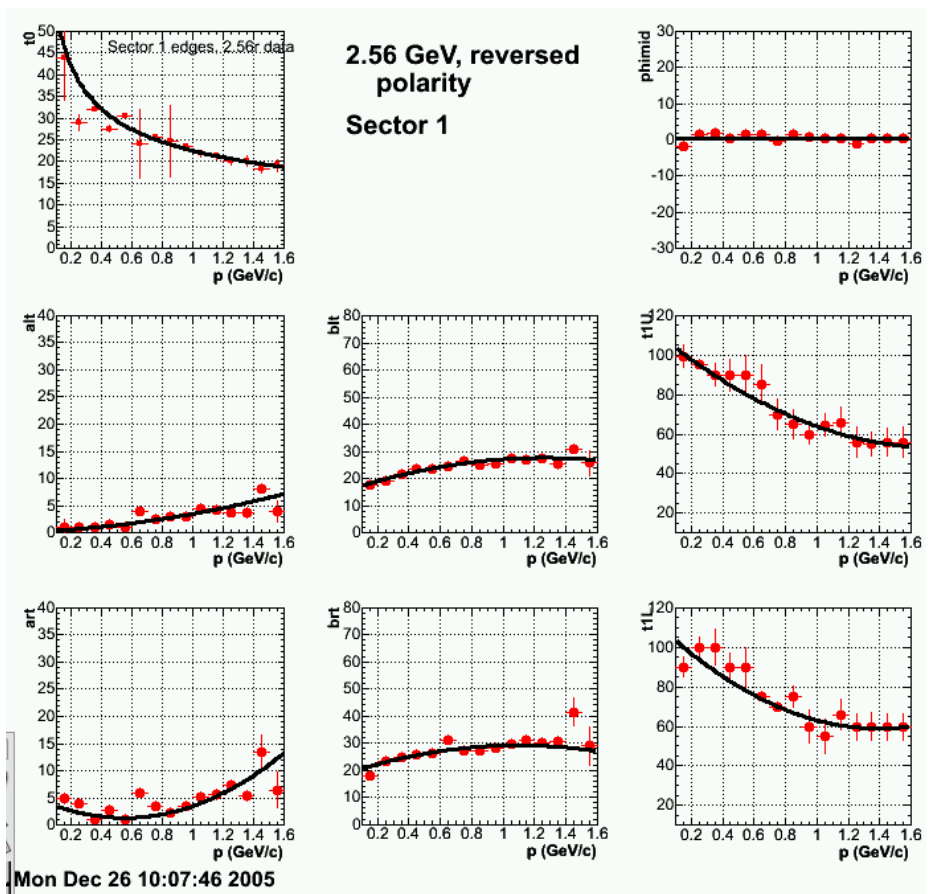

Fig 2. Same as Fig 1 with pol2 for alt, art, blt, brt.

Jerry Gilfoyle's Enotebook page 106 - 2.6 GeV reversed field pfid tests and ALTp (gpg)

[Modified Sat Jan 7 14:23:42 2006 (GMT) gpg]

Below are some results from applying the pfids for the 2.6 GeV, reversed field data.

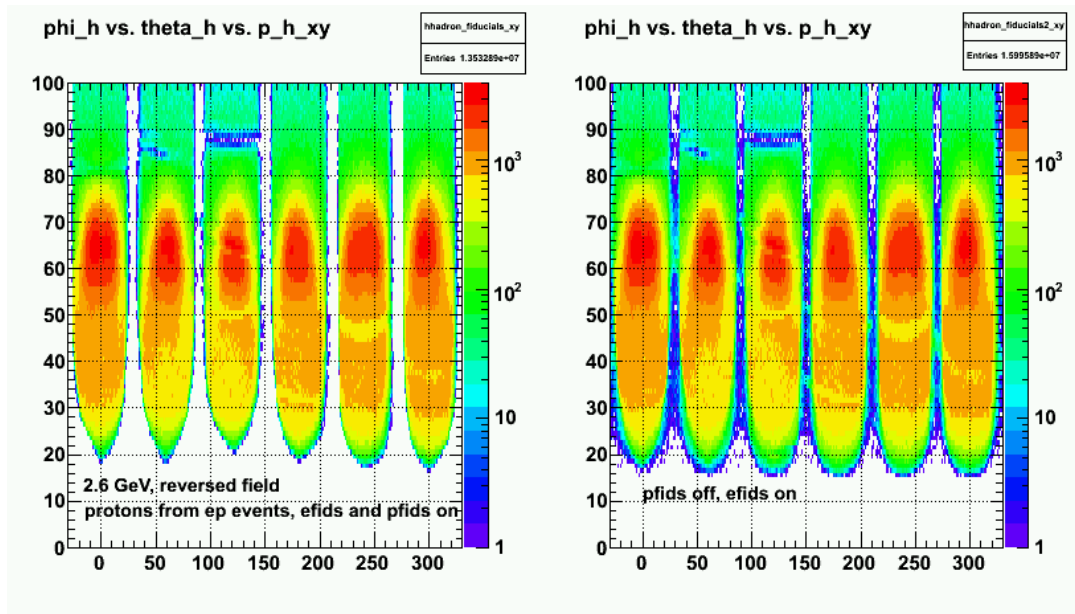

Fig 1. Comparison of the CLAS acceptance for the 2.6 GeV, reversed field data with the proton fiducials (and electron fiducials) on (left panel) and off (right panel).

Click [here](#) to view the object (ROOT C++ macro for Fig 1.) you uploaded.

The plot below shows a comparison of the projections of the 2D spectra in Fig 1 along the theta axis. The ratio of the counts is 1.059 so the pfids cut out only about 6% of the data.

Fig 2. Comparison of the angular distribution and number of counts with pfids (and efids) on (left panel) and off (right panel).

Click [here](#) to view the object (ROOT C++ macro for Fig 2) you uploaded.

The fiducial cuts have little effect on ALTp for quasielastic kinematics at 2.6 GeV, reversed field except for weakening the statistics. See Fig 3.

Fig 3. Comparing ALTp with efids and pfids on (red) and off (blue).

Fig 4. Comparing ALTp with efids and pfids on (red) and off (blue) using variable bin sizes.

Jerry Gilfoyle's Enotebook page 113 - Comparison of ALTp with HA curves (gpg)

[Modified Fri Feb 17 15:32:20 2006 (GMT) gpg]

The plots below show a comparison of the post-preliminary ALTp, quasielastic results with the old Arenhoevel calculations from 2003. The curves in Figures 1 and 3 are suspect, because I'm not sure I was getting everything right in going from HA's amplitudes (fL, fT, fLT, fTT, fLTp) to the asymmetry ALTp. See Figure 4-5 for more recent (2/10/06) calculations.

Fig 1. Comparison of ALTp in QE kinematics with Arenhoevel curves with leptonic tensor from Soong's thesis.

Click [here](#) to view the object (ROOT C++ macro for Fig 1) you uploaded.

Click [here](#) to view the object (Sample Mathematica notebook used to produce the Q2 averaged Arenhoevel curves in Fig 1.) you uploaded.

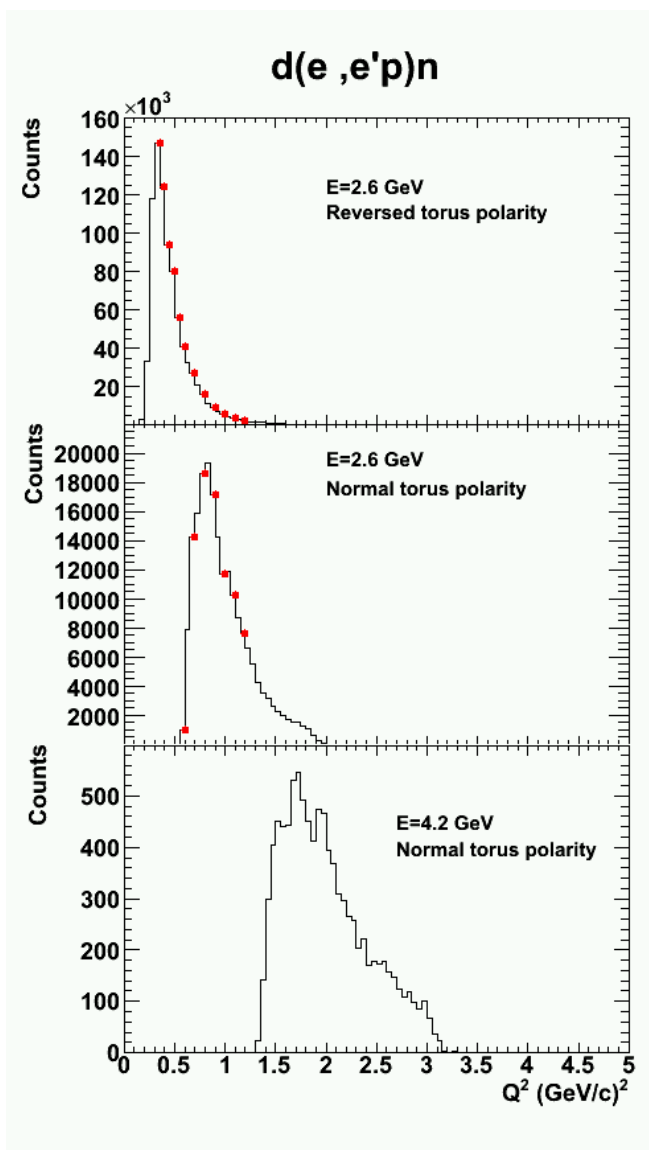

Fig 2. Q^2 distribution for epn events that went into QLTP in Fig 1. The red points are the Q^2 values where we have calculations from Arenhoevel

Click [here](#) to view the object () you uploaded.

Fig 3. Comparison using curves for single values of Q2 at the limits of the Q2 range for each set of running conditions.

Click [here](#) to view the object (ROOT C++ macro for Fig 3) you uploaded.

Plots below show HA calculations after fixing several stupid, little mistakes in my calculation of ALTp from HA amplitudes. In figure 4 the data go from about Q2=0.25-0.50 GeV2. I show the Q2=0.35 GeV2 calculation from HA because that is the lowest one I have. Compare Figures 405 with Figure 1.

Fig 4. Comparison of 2.6 GeV, reversed polarity data with HA calculations of ALTP at, roughly, the limits of the Q2 range for these running conditions.

Fig 5. Comparison of 2.6 GeV, normal polarity data with HA calculations of ALTP at, roughly, the limits of the Q2 range for these running conditions. This is really NORMAL torus polarity.

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

Click [here](#) to view the object (Mathematica notebook used to make the calculations for Figures 4-5.) you uploaded.

Studying the behavior of fLTp and ALTP as functions of Q2 and theta_pq. The thing that is surprising is that for previous published calculations the magnitude of the dip in ALTP drops from about 0.11 at Q2 = 0.13 GeV2 to ALTP=0.04 at Q2=0.22 GeV2 while my calculations of ALTP are always increasing (not decreasing) as Q2 increases. I don't understand this unless it means the non-helicity-dependent components are dropping much faster than fLTp, but why does it change from the behavior at lower Q2.

The plots below were made with the Mathematica notebook just above.

Fig 6. Fifth structure function amplitudes as a function of theta_pq for different Q2. The dashed curve at Q2 =0.22 GeV2 comes from an HA paper.

Fig 7. Fifth structure function asymmetry as a function of theta_pq for different Q2. The dashed curve at Q2 =0.22 GeV2 comes from an HA paper.

After some further thought I realized that using L,T, TT, and LT components of the cross section in the denominator of ALTp is wrong. It should just have the L and T parts. All the other pieces drop out because I integrate over all phi_pq and the TT and LT pieces will integrate to zero. In the plots below I have fixed this problem. Compare with figures 4-5 above. The HA calculations do better in general especially at small p_m. It's kind of amazing that at Q2 several times the maximum one that the calculations really don't do so bad.

Jerry Gilfoyle's Enotebook page 115 - Old Q2 dependence problem (gpg)

[Modified Fri Mar 10 01:47:40 2006 (GMT) gpg]

This is a reexamination of the old sensitivity to Q2 problem that I first discussed a year ago at the collaboration meeting (see talk on my research page) in Feb, 2005 and discussed some more at the June, 2005 collaboration meeting. The problem was that ALTp showed a striking dependence on the efids; with efids on the dip in the 2.6n ALTp was quite pronounced and then shrank by about a factor of two when the efids were turned off. This was surprising since the hope had been that by calculating ALTp (which is a ratio) the sensitivity to such stuff would be limited. What I realized a year ago was the turning on the efids had a significant effect on the Q2 distribution for the 2.6n data. This was part of the effect. I was also using fairly wide cuts to define quasielastic events (W cut) and neutrons (MM2 cut). One of the things we observed in the Feb, 2005 meeting was the dip in ALTp was most pronounced when the QE cut was centered on the proton peak and excluded the low and high W parts of the spectrum. It appears that there is a significant background from the resonance region the diluted ALTp with the wide QE cut that was reduced using the narrow W cut to define QE events. An analogous effect was seen in the neutron cut. When I made the MM2 cut more narrow, there was a noticeable reduction in the sensitivity to the electron fiducial cuts. The plots below are an exploration of the effect of different ranges for the MM2 cut defining the neutron. Again it appears that centering the MM2 right on the neutron peak reducing the dilution of the dip in ALTp. When I use MM2 ranges below the optimal one, the dip in ALTp is smaller, but still present though the statistics are weaker. When I include MM2 above the optimal one, the dip shrinks significantly. I also looked at ALTp extracted from the events EXCLUDED by the efids. In these data, at and below the optimal MM2 range for the neutron, the dip in the 2.6n ALTp is still there, but reduced in magnitude. For the MM2 range above the optimal one, the dip has gone away completely in the efid-excluded events.

After the study above I have lowered the low-end of the MM2 cut from 0.84->0.78. This improves the uncertainties a small amount without seriously changing the magnitude of the ALTp.

Jerry Gilfoyle's Enotebook page 117 - Extending neutron cut to lower MM2 (gpg)

[Modified Fri Mar 17 00:15:24 2006 (GMT) gpg]

I have investigated the effect of extending the MM2 on the neutron to lower MM2 to see the effect on ALTp. The effect is small. The magnitude of the asymmetry is a bit smaller at its maximum value and the uncertainty is a wee bit smaller. The plots below show the effect of the extended MM2 cut on the 2.6 GeV, reversed and normal polarity data. I haven't bothered with the 4.2 GeV data because the statistics are lousy. Compare these with entry [109](#).

2006-03-09 20:35:49

Jerry Gilfoyle's Enotebook page 118 - Study of effect of MM2 cut (gpg)

[Added Fri Mar 10 17:02:38 2006 (GMT) gpg]

Fig 1. MM2 distribution for ep events for 2.6 GeV, normal polarity data. The red lines define the MM2 discussed in the text.

Jerry Gilfoyle's Enotebook page 119 - Study of effect of MM2 cut (gpg)

[Modified Fri Apr 14 18:59:06 2006 (GMT) gpg]

We have investigated the sensitivity of ALTp to changes in the cut that defines a neutron in the MM2 (missing mass squared) distribution. The first plot below shows the MM2 distribution for the 2.6 GeV, normal polarity data for 2p coincidences. See the bottom of the page for other versions of these MM2 plots, ROOT macros, and histogram files.

Fig 1. MM2 distribution for ep events for 2.6 GeV, normal polarity data (left-hand panel) and 2.6 GeV, reversed polarity data (right-hand panel). The red lines define the MM2 cut for Fig 4 below and are discussed in the text.

The motivation for this study can be seen by comparing Figs 2-3. Figure 2 shows ALTp for a MM2 cut on the high side of the neutron peak. The different colors represent points where the electron and proton fiducials are turned on (red) and off (blue). Notice the significant change in ALT at p_m = 0.225 GeV/c. This is the type of behavior that has prompted some concern about the reliability of the ALTp measurement. The concern here is that some of the cross section from the resonance region may be contaminating the neutron peak here.

Fig 2. Comparison of ALTp with fiducial cuts on (red) and off (blue) for 0.90 < MM2 < 0.98 GeV2.

Fig 3 shows ALTp for a narrow MM2 cut centered on the neutron peak in Figure 1 (0.84 < MM2 < 0.92 GeV2). Recall that MM2 for a neutron is 0.88 GeV2. The effect of the fiducial cuts is much reduced at p_m = 0.225 GeV/c.

Fig 3. Comparison of ALTP with fiducial cuts on (red) and off (blue) for $0.84 < MM^2 < 0.92 \text{ GeV}^2$.

To study this effect a bit further, we extended the lower limit of the MM2 cut downward from $MM^2=0.84 \text{ GeV}^2$ to $MM^2=0.78 \text{ GeV}^2$. The result is shown in Figure 4. There is little difference between ALTP in Figs 3-4. We expect the background under the neutron peak from the resonance region will be less here (we're further away from the resonance region) so this MM2 range for the neutron is cleaner (and gives us a few more statistics).

Fig 4.

We finally decided to vary the range of the MM2 cut and see the effect on ALTP for the no-fids analysis. The results are in the two plots below. In Fig 5, effect of changing the range of the neutron MM2 cuts is shown. The three ranges correspond to the high-MM2 side of the neutron peak in the MM2 spectrum (blue), centered on the neutron peak (red), and the low-MM2 side of the neutron peak (black). We compared overlapping ranges for the MM2 to retain reasonable statistics. Off the peak, the magnitude of the asymmetry decreases.

Fig 5. Comparison of different ranges for the neutron MM2 cut for the 2.6 GeV, reversed polarity data. Electron and proton fiducials are turned off.

Click [here](#) to view the object (ROOT C++ macro for Fig 5.) you uploaded.

The same comparison is shown in Fig 6 for the 2.6 GeV, normal polarity asymmetry. The statistics are weaker so it's harder to draw any conclusions. The magnitude of the dip in ALTp at $p_m=0.22$ GeV/c is smaller for the high- and low-MM2 cuts, but all three results are consistent within the statistics.

Fig 6. Comparison of different ranges for the neutron MM2 cut for the 2.6 GeV, normal polarity data. Electron and proton fiducials are turned off.

Click [here](#) to view the object (ROOT C++ macro for Fig 6.) you uploaded.

The conclusions here are that to optimize the dip in ALTp use the centered MM2 cut, but there is not a big effect even when you extend the range of the MM2 cut to higher and lower MM2.

I re-analyzed the data with $MM^2 = 0.84-0.92$ GeV² and found the resulting ALTP to be very consistent with the other results for different MM2 neutron cuts. See Figure 10. The question now is where did the results in Figure 10 for $MM^2=0.84-0.92$ come from and why are they a little different?

Jerry Gilfoyle's Enotebook page 123 - first results on background simulation (gpg)

[Modified Wed May 17 03:28:48 2006 (GMT) gpg]

The plots below show the results for ALTp and alpha for a 3-hr simulation run.

Fig 1. Plots of ALTp (left panel) and alpha (background coefficient) x2 for 2.6r gsim with no fids.

Click [here](#) to view the object (ROOT C++ macro for fig 1.) you uploaded.

Fig 2. Same as Fig 1 with more events.

Click [here](#) to view the object (ROOT C++ macro for fig 2) you uploaded.

Draft of E5 elog entry.

Below is a comparison of the background asymmetry from the 2.6 GeV, reversed torus polarity data and a GSIM calculation. The calculation used the standard Celeg event generator, RECSIS (with Jeff's tcl input file), and my root code. In Fig 1, there is a significant (2-4%) background that is sensitive to the fiducial cuts. The [normal polarity data](#) also have such a background, but it is insensitive to the use of the fiducial cuts. This feature is not reproduced at all in the GSIM calculation in Fig 2. The background in the calculation is consistent with zero.

Fig 1. Comparison of background asymmetry with electron and proton fiducials on (red) and off(blue) for the 2.6 GeV, reversed polarity data.

Fig 2. Preliminary comparison of calculated background asymmetry with electron and proton fiducials on (red) and off(blue) for the 2.6 GeV, reversed polarity running conditions.

Click [here](#) to view the object (ROOT C++ macro for Fig 2.) you uploaded.

Fig 5. Same as Fig 1 with more events.

Click [here](#) to view the object (ROOT C++ macro for Fig 5) you uploaded.

I have observed that the recsis reconstruction only gets about 0.28 of the thrown events. This may be due to the small lower limit on the Q2 range in the celeg input in ftn15 which sends lots of tracks down the hole. try pushing that lower limit up to 0.5 to see if things improve. Below are the log files for node 0.

Click [here](#) to view the object (gsimulation log for Q2 rane 0.1-1.5 GeV2) you uploaded.

Click [here](#) to view the object (gsim log for Q2 rane 0.1-1.5 GeV2) you uploaded.

Jerry Gilfoyle's Enotebook page 124 - low reconstruction fraction in simulation (gpg)

[Modified Thu May 18 21:43:23 2006 (GMT) gpg]

I've noticed that with the first sim runs the fraction of events that are successfully reconstructed is low. Only about 60% of events pass the pattern recognition and 28% of events are getting through SEB. See recsis output below.

TRK_STATI	L: Cut#	Description	Value	Passed	%
TRK_STATI	L: 1	trk_evt: Ntrig (Nevt) >	0.0	120000	100.0
TRK_STATI	L: 2	ana_seg: Nevt w. segm =	5.0	71748	59.8
TRK_STATI	L: 3	trk_link: Nevt w. link =	5.0	71176	59.3
TRK_STATI	L: 4	ana_prfit: Nevt PR chi2 <	10.0	68206	56.8
TRK_STATI	L: 5	SEB_eid: Nevt SEB =	0.0	34489	28.7
TRK_STATI	L: 6	trk_dcam: Nevt w. LRseg=	4.0	34474	28.7
TRK_STATI	L: 7	trk_dcam: Nevt w. LRseg=	5.0	34344	28.6
TRK_STATI	L: 8	ana_fit: Nevt FF1 chi2 <	30.0	33967	28.3
TRK_STATI	L: 9	ana_fit: Nevt in TBT >	0.0	33967	28.3

WKB wonders if the lower limit of the Q2 range is so low that many events go down the hole. Change the Q2 range requested in celeg from 0.1->1.5 to 0.5->1.5 and things improve significantly.

TRK_STATI	L: Cut#	Description	Value	Passed	%
TRK_STATI	L: 1	trk_evt: Ntrig (Nevt) >	0.0	60000	100.0
TRK_STATI	L: 2	ana_seg: Nevt w. segm =	5.0	49145	81.9
TRK_STATI	L: 3	trk_link: Nevt w. link =	5.0	48806	81.3
TRK_STATI	L: 4	ana_prfit: Nevt PR chi2 <	10.0	48218	80.4
TRK_STATI	L: 5	SEB_eid: Nevt SEB =	0.0	41382	69.0
TRK_STATI	L: 6	trk_dcam: Nevt w. LRseg=	4.0	41379	69.0
TRK_STATI	L: 7	trk_dcam: Nevt w. LRseg=	5.0	41362	68.9
TRK_STATI	L: 8	ana_fit: Nevt FF1 chi2 <	30.0	41026	68.4
TRK_STATI	L: 9	ana_fit: Nevt in TBT >	0.0	41026	68.4

Now change the Q2 range selected in celeg from 0.5->1.5 to 1.0->2.0 and get the following. The percentages of successful reconstructions at the different stages now looks very good to me.

Run Number-	10	Event Number-	0	Total records seen-	7002
TRK_STATI	L: Cut#	Description	Value	Passed	%
TRK_STATI	L: 1	trk_evt: Ntrig (Nevt) >	0.0	7000	100.0
TRK_STATI	L: 2	ana_seg: Nevt w. segm =	5.0	6156	87.9
TRK_STATI	L: 3	trk_link: Nevt w. link =	5.0	6075	86.8
TRK_STATI	L: 4	ana_prfit: Nevt PR chi2 <	10.0	6018	86.0
TRK_STATI	L: 5	SEB_eid: Nevt SEB =	0.0	5512	78.7

TRK_STATI	L: 7	trk_dcam: Nevt w. LRseg=	5.0	5510	78.7
TRK_STATI	L: 8	ana_fit: Nevt FF1 chi2 <	30.0	5460	78.0
TRK_STATI	L: 9	ana_fit: Nevt in TBT >	0.0	5460	78.0

Jerry Gilfoyle's Enotebook page 125 - vx, vy, vz distribution (gpg)

[Modified Thu Jul 13 19:21:17 2006 (GMT) gpg]

Examine the distribution of vx, vy, and vz as a possible clue to the nature of the background asymmetry. Look at electron singles first at 2.6 GeV, reversed field.

Fig 1. Distribution of the x component of the vertex position. This odd looking distribution can be ignored because it is not a well defined quantity because the track is by definition a 2-dimensional object (we chose y and z) so this distribution has no meaning.

Fig 2. Distribution of the y component of the vertex position.

Fig 3. Distribution of the z component of the vertex position.

Now do electron vertex position distributions for e-p coincidences.

Fig 4. Distribution of the y component of the vertex position.

Fig 5. Distribution of the z component of the vertex position.

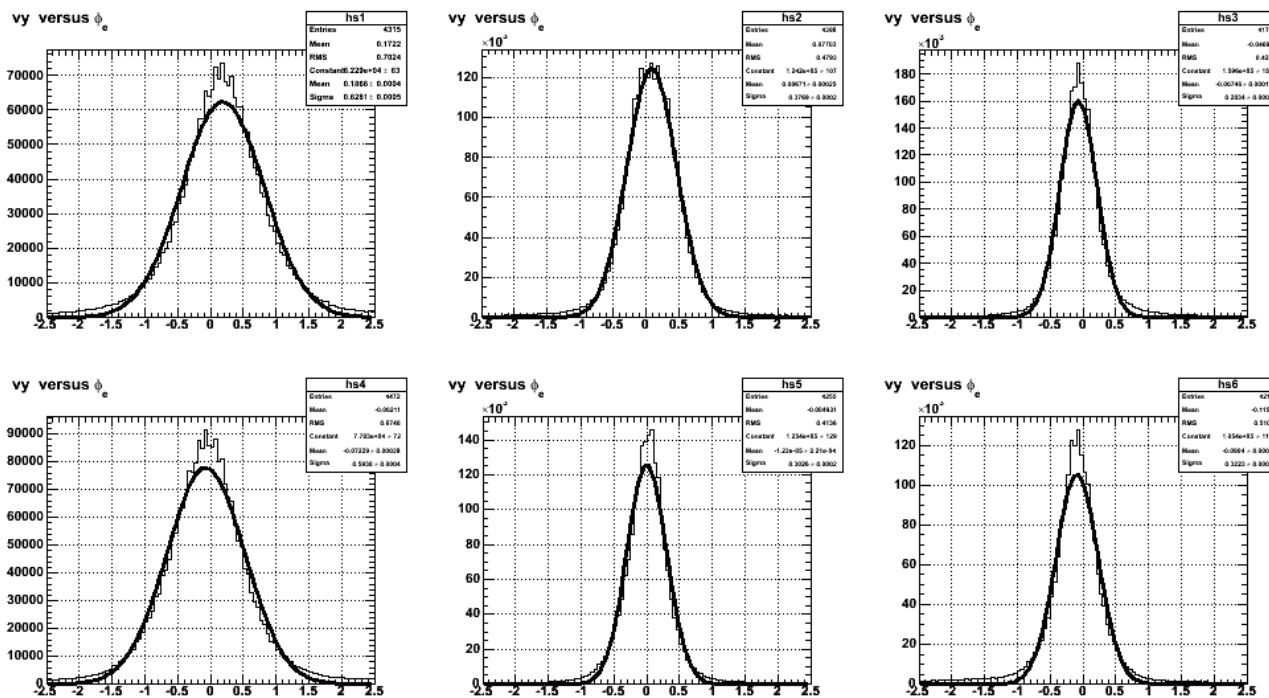

Fig 6. Plot of distribution of vy sector by sector for ep coincidences.

Click [here](#) to view the object (PS file of Fig 6.) you uploaded.

Click [here](#) to view the object (ROOT C++ macro for previous plot) you uploaded.

Plots 7-9 claim to be for epn coincidences, but the MM2 neutron cut was set wrong. Figs past Fig 9 have the proper cut.

2008-05-18 21:50:08

Fig 7. Plot of distribution of vz sector by sector for epn coincidences.

2008-05-18 21:53:08

I'm worried about the possible effect of the long tails in v_y on ALTp so extract ALTp with a cut on v_y .

Fig 10. ALTp with an additional cut applied so $-0.5 \text{ cm} < v_y < 0.5 \text{ cm}$.

2006-06-02 16:13:00

Fig 4. ϕ_{pq} dependence from PART banks.

2006-06-02 16:22:58
Fig 5. phi_pq dependence from PART banks.

Fix a couple of things and ALTp starts to look vaguely correct. I now see an ALTp that is consistent with the input. The amplitude was set to 0.8 for all p_m. I DON'T understand the variation in ALTp about 0.8, but that variation is small (percentage-wise) compared to the uncertainties in our data. I check the background asymmetry and it was consistent with zero for all p_m.

2006-06-03 13:08:58
Fig 6. ALTp plot for PART banks after finally getting things vaguely correct. The electron phi is set to zero here.

Click [here](#) to view the object (ROOT histogram file for fig 6) you uploaded.
 Click [here](#) to view the object (ROOT histogram file for fig 6) you uploaded.

The next figure is for phi_e=0.0 and with a large amplitude (0.8) on ALTp that is fixed for all p_m. I see the expected sinusoidal oscillation in phi_pq for a given p_m bin.-

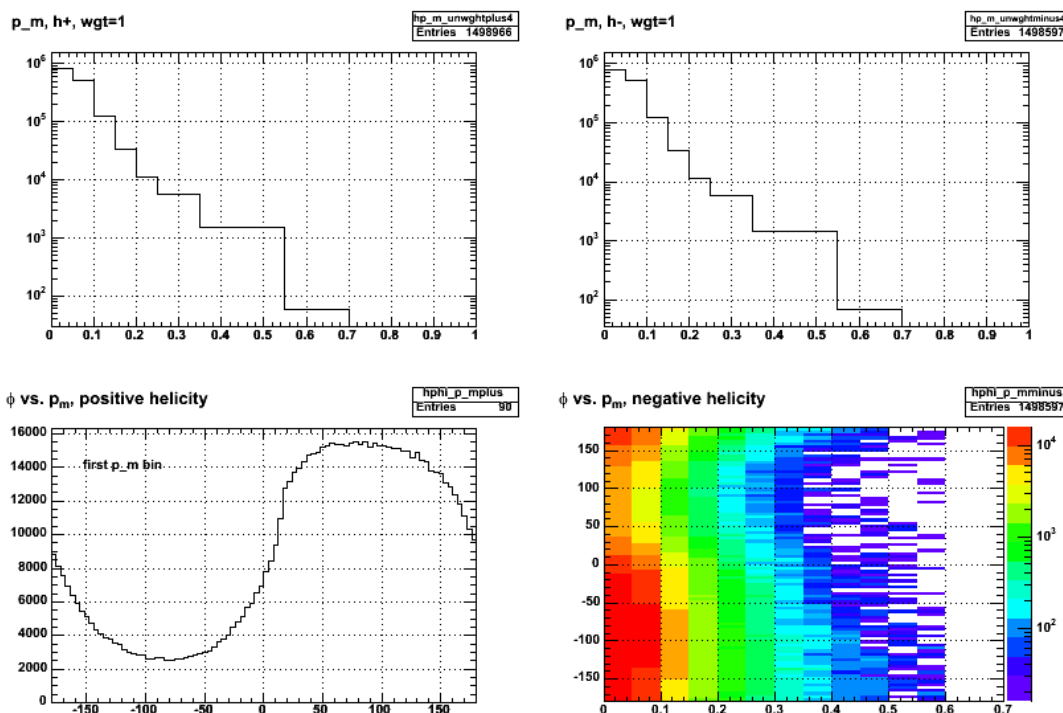

Fig 7. Plots from sim with $\phi_e=0$.

For the next plot fix $\phi_e=0.0$ and $\phi_{pq}=90$ deg. The sinusoidal oscillation in the ϕ_{pq} vs p_m disappears, but it is NOT a spike as I expected. This may be ok. Even if I fix $\phi_e=0.0$ and $\phi_{pq}=90.0$, the proton will still have a range of momenta and θ_{pq} taken from the Hulthen distribution. That single ϕ_{pq} will get boosted into a range of ϕ_p angles in the lab. Also the electron kinematics is independent of our choices for ϕ_{pq} so that will also smear things out. Does the boost smear things out?

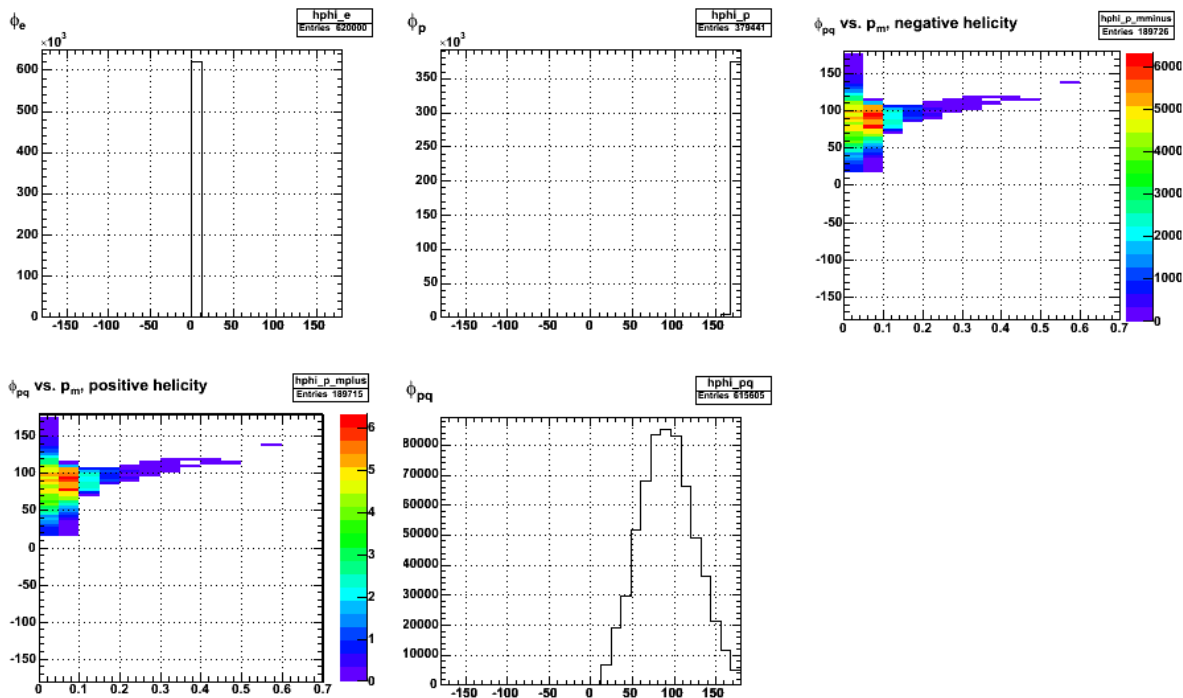

Fig 8. lots from sim with $\phi_e=0$ and $\phi_{pq}=90$ deg.

Click [here](#) to view the object (ROOT C++ macro for fig 8) you uploaded.

Click [here](#) to view the object (ROOT histogram file for Fig 8) you uploaded.

Next I fixed $\cos(\theta_{pq}) = 0.99$ and $p_{fermi} = 0.05$ and got the following plot. Happily, the width of the ϕ_{pq} distribution shrinks to zero it appears, but it's

now centered at phi_pq ~ 10 deg, not 90 deg???

2006-06-03 16:59:36
Fig 9. ϕ_{pq} vs. p_m with $\cos(\theta_{pq})=0.99$, $p_{fermi}=0.05$, $\phi_e=0.0$, $\phi_{pq}=90$ deg.

Click [here](#) to view the object (ROOT PART histogram file for Fig 10) you uploaded.

Jerry Gilfoyle's Enotebook page 128 - Testing ϕ_{pq} distribution in queeg (gpg)

[Modified Fri Jul 14 22:54:17 2006 (GMT) gpg]

The first plot shows 2×10^6 events histogrammed directly from queeg when they were generated. Why isn't this flat? I selected events that passed Jeff's cuts so this distribution has the acceptance in it at some level.

Tue Jul 11 22:55:38 2006

Fig 1. ϕ_{pq} distribution from queeg (2 million events).

Click [here](#) to view the object (ROOT C++ macro for fig 1) you uploaded.

Yikes, the following result looks awful!

Wed Jul 12 08:07:28 2006

Fig 2. ϕ_{pq} distribution after putting in random ϕ rotation of electron and other vectors??!

Click [here](#) to view the object (ROOT C++ macro for fig 2) you uploaded.

Pilot error as usual; bug in code. Following plot is for 1/10 the number of events, but is consistent with Fig 1.

Wed Jul 12 10:40:28 2006

Fig 3. Corrected plot of phi_pq distribution of thrown events after the random rotation in phi_e in queeg.

Click [here](#) to view the object (ROOT C++ macro for fig 3) you uploaded.

The plot below shows a comparison of thrown and accepted events from queeg. It raises some questions.

1. Why are so many events thrown out? The ratio of thrown to accepted seems awfully high?
2. Why do the thrown events have so much structure in the phi distribution. i would have thought the distribution of thrown events would have been flat while the accepted events would have more structure in it since it has acceptance effects.

Fri Jul 14 11:58:05 2006

Fig 4. Comparison of thrown and accepted events from queeg.

Click [here](#) to view the object (ROOT CINT macro for Fig 4) you uploaded.

Click [here](#) to view the object (gzipped tar file with input and CINT macros for Fig 4) you uploaded.

Tests of distributions at the end of generating the event look random as they should. the phi distribution of phi_pq shown above is not flat. This, I guess, is the effect of a random phi distribution in the proton fermi motion getting translated in the phi_pq distribution.

Fri Jul 14 18:46:18 2006

Fig 5. Test of ϕ_e distribution after generating event.

Jerry Gilfoyle's Enotebook page 129 - fixed ALTp=0.2 tests (gpg)

[Modified Wed Jul 19 01:28:27 2006 (GMT) gpg]

To test the consistency of the simulation of the non-zero helicity asymmetry, I used a fixed asymmetry in queeg and ran it through the simulation and analysis codes. The first plot is an analysis of the PART bank, the thrown events without being sent through GSIM. The fit is just a straight line to show ALTp is consistent with the input of a fixed asymmetry. The disturbing thing is this asymmetry should be flat (it is) at a value of 0.2 instead of 0.1. It's asymmetry is half what it is supposed to be. NOTE There was a problem with the perl script and the negative helicity results were getting overwritten so figures 1-3 should be ignored.

2006-07-17 09:55:20

Fig 1. ALTp for 2.6r, PART bank analysis, no efids or pfids.

Click [here](#) to view the object (ROOT CINT macro for Fig 1.) you uploaded.

Click [here](#) to view the object (ROOT histogram file for fig 1) you uploaded.

The second plot is for the EVNT analysis. It's ALTp after the events above goign through GSIM. The large difference in ALTp between the two is very disturbing. The immediate implication is that there is a large acceptance dependence in ALTp. Uuggghh!

2006-07-17 10:05:44

Jerry Gilfoyle's Enotebook page 130 - Checking ALTp=0.2 results (gpg)

[Modified Sat Jul 22 02:08:34 2006 (GMT) gpg]

Check the results of the previous entry in a more coherent sequence. The acceptance corrected asymmetry ALTp is defined in the following way

$$A'_{LT} = \langle \sin \phi_{pq} \rangle_+ - \langle \sin \phi_{pq} \rangle_-$$

$$A'_{LT} = \frac{1}{P_e} \frac{\frac{\sum_{h=+1} \sin \phi_{pq}}{\text{Acc}_+(\sin \phi_{pq})}}{\frac{N_+}{\text{Acc}_+(normal)}} - \frac{\frac{\sum_{h=-1} \sin \phi_{pq}}{\text{Acc}_-(\sin \phi_{pq})}}{\frac{N_-}{\text{Acc}_-(normal)}}$$

where P_e is the beam polarization, *normal* refers to event weighting of unity, and *Acc* is the acceptance for that particular bin in missing momentum p_m , Q_2 , and W . The figure below shows the ratio of the acceptance corrections for the positive polarity data from the simulation.

Fig 1. Ratio of $\sin(\phi_{pq})$ to normal weighted acceptances for positive helicity and 2.6 GeV, reversed polarity data.

Click [here](#) to view the object (ROOT CINT macro for Fig 1.) you uploaded.

Jerry Gilfoyle's Enotebook page 131 - Exclurad tests (gpg)

[Added Sat Jul 29 01:23:53 2006 (GMT) gpg]

Below are links to files with results from my exclurad radiative correction tests.

Jerry Gilfoyle's Enotebook page 132 - p_m dependent tests (gpg)

[Modified Thu Aug 10 21:08:51 2006 (GMT) gpg]

Below are some (confusing) results playing around with different forms of the thrown ALTp.

Fig 1. ALTp for amp = helicity_sign*pfermi2????

Click [here](#) to view the object (ROOT CINT macro for Fig 1) you uploaded.

The problem with my results up to now is that i was basing everything on the fermi momentum and it should be based on the missing momentum in the $d(e,e'p)n$ reaction. I have modified queeg so that the modification of ϕ_{pq} depends on p_m and not on the fermi momentum. Some first results from those changes are shown in Fig 2. The amplitude for the fifth structure function (the piece that depends on $\sin(\phi_{pq})$) is the following

amp = -0.3 $p_m < 0.1$ GeV/c
 amp = +0.1 $p_m > 0.1$ GeV/c

which is precisely reproduced for the thrown events.

2006-08-08 13:45:58
 Fig 2. ALTp for thrown events with queeg. Based on 150,000 events per node.

Click [here](#) to view the object (ROOT histogram file for accepted events for Fig 3) you uploaded.

Click [here](#) to view the object (ROOT histogram file for thrown events for Fig 3) you uploaded.

The stuff above looks good though the acceptance dependence of ALTP is surprising.

Try another, more realistic, amplitude function. The one I used is

$$\text{amp} = -((0.05*x) + (-8.0*x*x) + (-5.0*x*x*x)) * \exp(-10.0*x)$$

where the parameters were picked to at least roughly look like the 2.6r data. The results for the thrown events are shown below. The black curve is a plot of the input asymmetry above drawn on top of the asymmetry extracted from the PART bank (the thrown events) generated by QUEEG.

2006-08-08 17:46:08

Fig 4. ALTP for thrown events with a different input asymmetry for 15,000 events per node. The black curve is the function used to determine the input asymmetry in QUEEG.

Now do a longer run.

Fig 5. $ALTP$ for thrown events with a different input asymmetry for 55,000 events per node. The black curve is the function used to determine the input asymmetry in QUEEG.

Holy Shit! What is this???

The gsm output files for the analysis of Figs 5-7 are in /data3/e5/sim/run4.

Fig 6. $ALTP$ for accepted events with a different input asymmetry for 55,000 events per node. The black curve is the function used to determine the input asymmetry in QUEEG.

ALTp vs. p_m , acceptance corrected

Fig 7. Acceptance corrected ALTp. Compare with Fig 6

Click [here](#) to view the object (ROOT CINT macro for Fig 7) you uploaded.

Set the amplitude of the fifth structure function to zero to see if the distortion of the accepted data persists. It does! This is a disaster! Maybe not. It just may be the asymmetry is zero which would surprise lots of theorists. The results in Fig 8 are for fiducial cuts off. Putting the fiducial cuts on changes the asymmetry just slightly and well within the uncertainty.

2006-06-10 00:03:09

Jerry Gilfoyle's Enotebook page 133 - queeg modifications (gpg)

[Modified Fri Aug 18 03:45:47 2006 (GMT) gpg]

I have modified Jeff's event generator QUEEG in order to study the effect of the CLAS acceptance on the fifth structure function analysis. The goal here is to control the size of the $\sin(\phi_{pq})$ dependent part of the $D(e,e'p)n$ cross section. By controlling this part of the cross section we can compare the value used in the event generator with the final results of the analysis chain. First, let me summarize how QUEEG generates events.

1. Pick a magnitude for the Fermi momentum of the proton from the Hulthen distribution and give it a random direction in the laboratory frame.
2. Transform to the (now moving) rest frame of the proton. Calculate a new beam energy for the incoming electron relative to this new rest frame of the proton.
3. Select the angle of the scattered electron based on the cross section for elastic scattering at this new electron energy.
4. Transform the angle of the scattered electron from the proton rest frame into the lab frame.
5. Determine the scattered electron energy for the $d(e,e'p)n$ reaction using the known momentum of the neutron (i.e. the negative of the fermi momentum of the proton picked in part 1).
6. Calculate the q 3-vector (3-momentum transfer), p_p (proton 3-momentum), *etc.* in the lab for this quasi-elastic scattering.
7. Randomly select the lab azimuthal angle (ϕ) and rotate the 3-vectors for the momentum transfer, proton, and scattered electron momenta and you're done.

The modifications I have made have been to change the angle ϕ_{pq} , the angle between the scattering plane (defined by the incoming and outgoing electron 3-momenta) and the reaction plane (defined by the proton and momentum transfer 3-vectors). The direction of the momentum transfer, the magnitude of the proton 3-vector, and the angle θ_{pq} are unchanged. The modifications are made steps 6 and 7 above.

1. Calculate the missing momentum based on the known momentum of the beam, scattered electron and proton. This, of course, agrees with the neutron momentum mentioned in step 5.
2. Rotate coordinates so that the z-axis is now in the direction of the 3-momentum transfer q . The y-axis stays the same for this new coordinate system and the lab system.
3. Randomly generate a new ϕ_{pq} based on a sinusoidal distribution with an amplitude that depends on the magnitude of the missing momentum.
4. calculate a new missing momentum 3-vector with the same magnitude as in part 1, but with a different ϕ_{pq} using the result of part 3.
5. Rotate back to the lab coordinate system with the z-axis along the beam.
6. Calculate a new proton 3-vector using the original beam, target, and scattered electron momenta and the modified neutron momentum.

The gsim/gpp files used in the analysis above are stored in /data3/e5/sim/run5/. As usual it was pilot error. I had modularized the analysis code so that I could use the same functions to analyse the EVNT banks and the PART banks. One module defined the way to calculate the errors for the histograms used to extract ALTp. Well, bonehead me forgot to call that function in the EVNT analysis so the uncertainties for the EVNT analysis were wrong. When corrected I get the results below when the amplitude of the asymmetry is set to zero.

Fig 6. Comparison of ALTp for accepted and thrown events after correcting the calculation of the uncertainties for the EVNT bank analysis. The numbers for each curve are the results of MINUIT fits to a flat line to demonstrate the data are consistent with zero.

More accumulation. This is for runs 7-11 + 17.

Fig 2. Accumulated ALTp for simulated events with no offsets.

Click [here](#) to view the object (ROOT CINT file for Fig 2) you uploaded.

Click [here](#) to view the object (ROOT histogram file for Fig 2) you uploaded.

The plot below shows the results of extracting ALTp from simulated events analyzed with the same codes used for the data analysis. The expectation is that by using a ratio to extract and ALTp that it should be independent of acceptance corrections. To test this we have used an arbitrary function (the red curve in Figure

1) as input for ALTp in the simulation and then compared the results extracted from the simulation with that original function (the blue 'data' points in Figure 1. There is rough agreement over most of the range of p_m between the black curve and the simulation, but some of the simulated points sit below the curve in the range $p_m = 0.1-0.2$ GeV/c.

2006-11-16 19:57:26

Figure 1. Comparison of ALTp curve used as input to GSIM (black curve) and the results of the simulation(blue points) for 2.6 GeV, reversed field data.

Click [here](#) to view the object (ROOT CINT macro for fig 1) you uploaded.

Click [here](#) to view the object (ROOT histogram file for Fig 1) you uploaded.

To make a better comparison between the input to GSIM and the simulated results, we averaged the input function over the same bins used in the analysis. The results are shown in Figure 2. There is good agreement over most of the range of p_m , but the points at 0.125 GeV/c and 0.175 GeV/c are still low.

2006-11-16 22:21:16

Figure 2. Comparison of the GSIM ALTp input curve averaged over the same bins used in the analysis with the results of the simulation.

Jerry Gilfoyle's Enotebook page 136 - $\cos(\phi)$ and $\cos(2\phi)$ simulations (gpg)

[Modified Tue Oct 10 17:55:52 2006 (GMT) gpg]

The plots below show the $\cos(\phi)$ and $\cos(2\phi)$ asymmetries with zero input asymmetry, but with shifts in the vertex positions of the tracks to mock up offsets in the CLAS sectors.

Fig 1. False asymmetry for $\cos(\phi)$ from shifts in vertex positions.

Jerry Gilfoyle's Enotebook page 137 - Record of saved simulation data (gpg)

[Modified Wed Jul 25 22:26:52 2007 (GMT) gpg]

Below is a listing of directories on the cluster disks and some notes on the nature of the simulation.

In /data3/gilfoyle:

- minus1 - used QUEEG to generate events. deleted 7/25/07.
- minus2 - used QUEEG to generate events. deleted 7/25/07.
- minus3 - used QUEEG to generate events. deleted 7/25/07.
- plus1 - used QUEEG to generate events. deleted 7/25/07.
- plus2 - used QUEEG to generate events. deleted 7/25/07.
- plus3 - used QUEEG to generate events. deleted 7/25/07.
- bothrun1
- bothrun12 - 10/01/06, sector shifts in 'by hand', calculation of uncertainties for cos(phi) and cos(2phi) histograms is WRONG, p_m threshold NOT set to zero. Includes positive and negative helicities. used QUEEG to generate events.
- bothrun13 - 10/05/06, sector shifts in 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms is WRONG, p_m threshold set to zero. Includes positive and negative helicities. used QUEEG to generate events.
- bothrun14 - 10/09/06, sector shifts in 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to zero. Includes positive and negative helicities. used QUEEG to generate events.
- bothrun15 - 10/10/06, sector shifts in 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to zero. Includes positive and negative helicities. used QUEEG to generate events.
- bothrun16 - 10/11/06, sector shifts in 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to zero. Includes positive and negative helicities. used QUEEG to generate events.
- bothrun17 - 10/19/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to 0.2!!!!!! Includes positive and negative helicities. used QUEEG to generate events.
- bothrun18 - 11/15/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to 0.2!!!!!! Includes positive and negative helicities. used QUEEG to generate events.
- bothrun19 - 11/15/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to 0.45!!!!!! Includes positive and negative helicities. used QUEEG to generate events.
- bothrun20 - 11/18/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to 0.45!!!!!! Includes positive and negative helicities. used QUEEG to generate events.
- bothrun21 - 11/22/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to 0.45!!!!!! Includes positive and negative helicities. used QUEEG to generate events. Turned off gpp to see if shift in ALTp at low p_m is still there.
- bothrun22 - 11/27/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned off gpp to see if shift in ALTp at low p_m is still there.
- bothrun23 - 11/30/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned off gpp to see if shift in ALTp at low p_m is still there.
- bothrun24 - 12/01/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned off gpp to see if shift in ALTp at low p_m is still there.
- bothrun25 - 12/04/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option.
- bothrun26 - 12/20/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Put in OPPOSITE for the asymmetry so ALTp = 0.10 instead of -0.1 as in the simulations above. the new line in queeg is the following.

```
float amp = helicity_sign*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

- bothrun27 - 12/22/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Scaled ALTp by one-half. the new line in queeg is the following.

```
float amp = 0.5*helicity_sign*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

- bothrun28 - 12/29/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Scaled ALTp by one-half with opposite (and positive) sign compared with bothrun27. the new line in queeg is the following.

```
float amp = helicity_sign*0.5*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

NOTE It looks like run 28 had the same ALTp scale factor (=0.5) as run 27!!!! Damn!!!

- bothrun29 - 12/31/06, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Set scale = +0.5. the new line in queeg is the following.

```
float amp = -helicity_sign*0.5*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

Accidentally deleted the root files.

- bothrun30 - 01/02/07, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Set scale = +0.0. the new line in queeg is the following.

```
float amp = -helicity_sign*0.0*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

- bothrun31 - 01/03/07, turned sector shifts OFF 'by hand' and calculation of uncertainties for cos(phi) and cos(2phi) histograms corrected, p_m threshold set to **0.0!** Includes positive and negative helicities. used QUEEG to generate events. Turned on gpp with -R24517 option. Set scale = +0.5. the new line in queeg is the following.

```
float amp = -helicity_sign*0.5*((0.05*pfermi2) + (-8.0*pfermi2*pfermi2) + (-5.0*pfermi2*pfermi2*pfermi2))*exp(-10.0*pfermi2);
```

Jerry Gilfoyle's Enotebook page 138 - Background asymmetry (gpg)

[Modified Fri Oct 13 20:33:31 2006 (GMT) gpg]

First look at the background asymmetry extracted from different helicity beams.

Fig 1. Comparison of thrown (left) and simulated (right) events with the vertex shift on, ALTp asymmetry on, for run 14.

Click [here](#) to view the object (ROOT CINT macro for Fig 1) you uploaded.

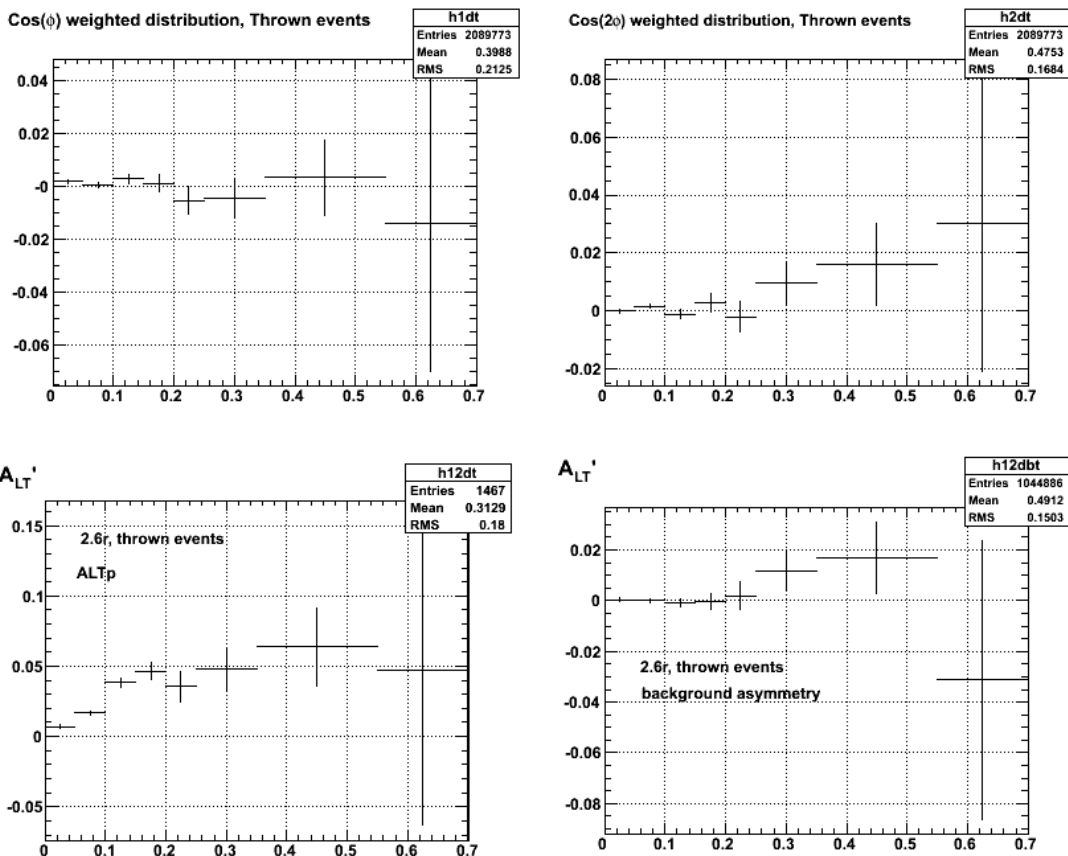

Fig 2. Asymmetries for thrown events for run 14 with ALTp asymmetry turned on, no p_m threshold, no ALT or ATT asymmetries

Click [here](#) to view the object (ROOT CINT macro for Fig 2) you uploaded.

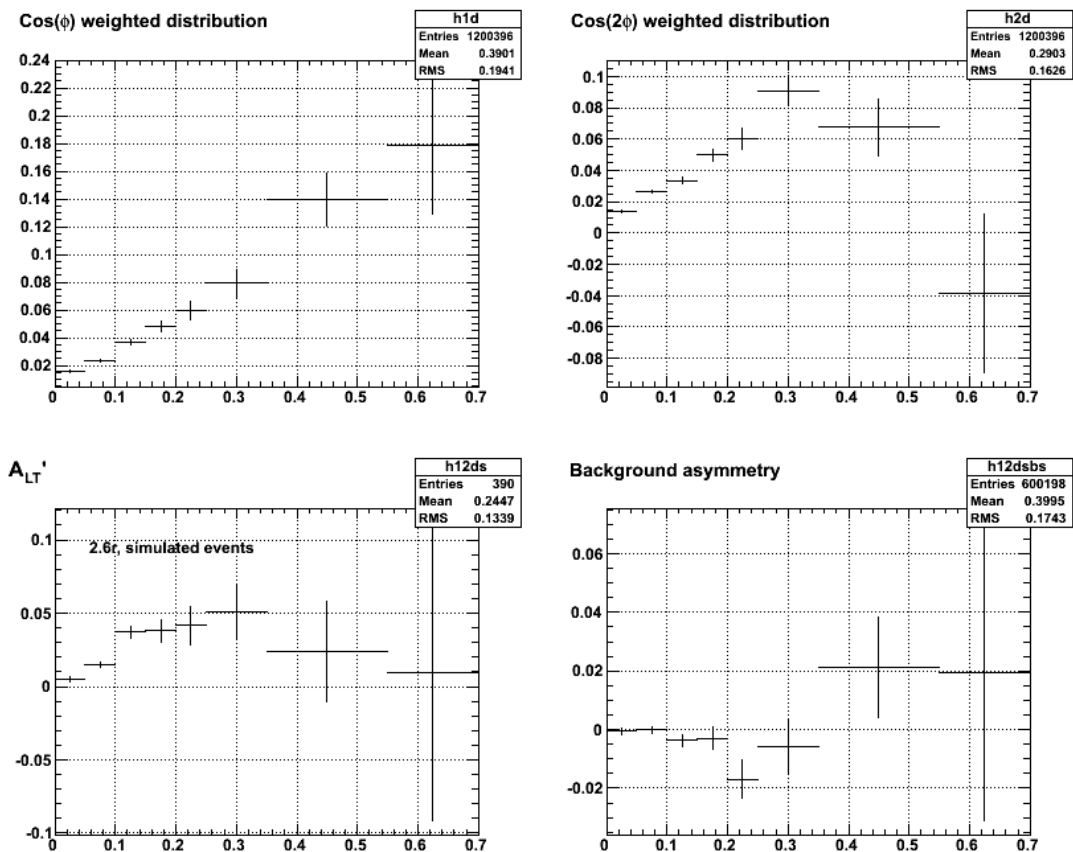

Fig 2. Asymmetries for simulated events for run 14 with ALTp asymmetry turned on, no p_m threshold, no ALT or ATT asymmetries.

Click [here](#) to view the object (ROOT CINT macro for Fig 3) you uploaded.

The results for the background asymmetry in Fig 3 are surprising since we see significant background asymmetry in the data, in the simulation of ATT and ALT, but not in the simulation of the background asymmetry using vertex offsets extracted from the data. The results for the data are shown in Fig 4.

Fig 4. Background asymmetry from the data for 2.6 GeV, reversed polarity. See entry 110.

I re-analyzed the run13 data with the correct calculation of the uncertainties and added it to the gsim data for runs 14-16 and get the following. it's surprising that we get such a large false asymmetry in ALT and ATT from the vertex shifts, but there is little background asymmetry in ALTp. Ask Harut about this.

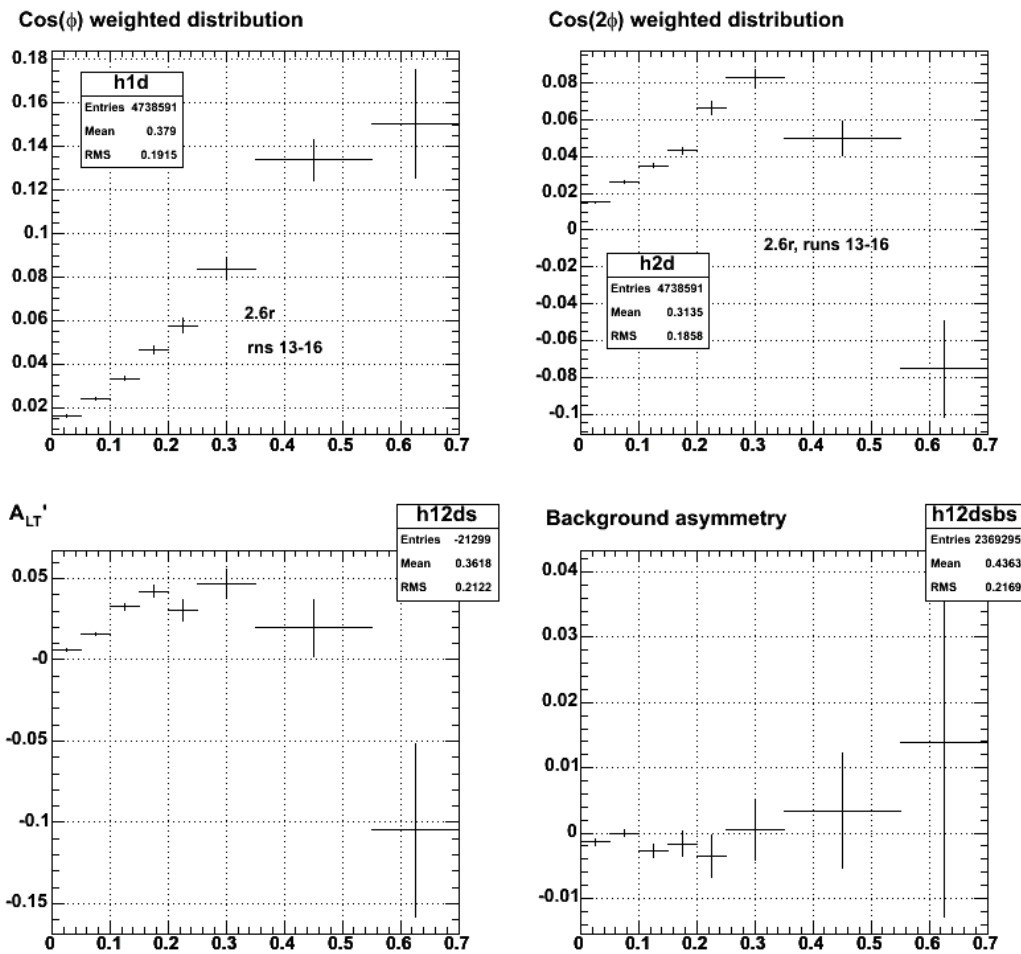

Fig 5. Asymmetry results for gsim runs 13-16 with no p_m threshold, ALTP turned on, vertex shifts turned on.

Jerry Gilfoyle's Enotebook page 139 - re-analysis of /data3/gilfoyle/bothrun13 (gpg)**[Modified Fri Oct 13 20:13:50 2006 (GMT) gpg]**

I generated some new scripts that analyze the gsim data from a previous simulation run for the EVNT banks. The scripts are analyze_sim.pl which than calls no_gsim_on_node.pl. The histogram file for the data in /data3/gilfoyle/bothrun13 is below.

Click [here](#) to view the object (histogram file for the data in /data3/gilfoyle/bothrun13) you uploaded.

Jerry Gilfoyle's Enotebook page 140 - Bin Correction factors (gpg)

[Modified Thu Jan 4 04:27:02 2007 (GMT) gpg]

In my last week before the APS meeting angst I am suddenly worried about being asked about bin correction factors so I calculated some. For guidance I used some Hall C stuff at the following location.

<http://www.krl.caltech.edu/~johna/thesis/node65.html>

I then used the functional form for the simulation of ALTP and compared what I get from using the value of the curve at the center of the bin (I used the real bin sizes from the analysis) to the integral of the function over the bin and divided by the bin size. The results are shown in Figure 1.

Fig 1. Difference between value of ALTP function that is input to simulation at the center of each bin and the properly averaged value as a function of the Fermi momentum.

Click [here](#) to view the object (The *Mathematica* notebook is here.) you uploaded.

Next, I took the value from each bin AFTER having run through the simulation and subtracted off the value from the function averaged over the bin. Things look GOOD! See Fig 2. <

Fig 2. Difference between the simulated value for ALTP and the original input function averaged over the bin.

Click [here](#) to view the object (Updated *Mathematica* notebook is here.) you uploaded.

Fig 3. Comparison of bin-averaged input curve with results of gsim run with gpp turned off.

Click [here](#) to view the object (ROOT CINT macro for Fig 3.) you uploaded.

Click [here](#) to view the object (ROOT histogram file used for fig 3) you uploaded.

Click [here](#) to view the object (ROOT CINT macro for Fig 4) you uploaded.

Click [here](#) to view the object (ROOT histogram file for fig 4) you uploaded.

The plot below is very disturbing because of the large excursion from zero in the same range as the dip we see in the data!!!

2006-12-20 14:23:46

Fig 5. Comparison of run 26 results with input curve and ALTp scale=-1.0.

Click [here](#) to view the object (ROOT CINT macro for fig 5) you uploaded.

I've changed the sign of the input ALTp to see if the effect seen in Fig 5 holds up. It appears to go away (see fig 6 below), but the deviation from zero in the second p_m bin persists and has now flipped sign when I flipped the sign in the ALTp input to the simulation.

2006-12-20 14:50:55

Jerry Gilfoyle's Enotebook page 141 - New calculation from Sabine Jeschonneck (gpg)

[Modified Fri Nov 17 03:36:06 2006 (GMT) gpg]

Sabine recently sent me her latest calculation of the structures functions of the deuteron using the Generalized Eikonal Approximation. She has made a calculation for $Q^2=1.1 \text{ GeV}^2$ which is a bit above the average value of the Q^2 for the 2.6 GeV, normal-field data set. The results are shown in Figure 1 below along with some older curves. The red curve is from Sabine. She has not made a calculation for the lower- Q^2 data set yet because she does not feel her calculation is valid in that range. The green curves are from Jean-Marc Laget and they are also calculations for a single Q^2 at the average Q^2 value for each data set. The black curve is an older calculation from Arenhoevel that is averaged over the Q^2 distribution for these data.

Comparison of AL_{T_p} for the two 2.6-GeV data sets. The curves are explained in the text.

Jerry Gilfoyle's Enotebook page 142 - Check on EC pion signal (gpg)

[Modified Fri Dec 15 14:51:19 2006 (GMT) gpg]

The plots below are in response to questions from the GMn review committee. We want to check the uniformity of the EC response to positive and negative pions.

Jerry Gilfoyle's Enotebook page 143 - check on UVW strips (gpg)

[Modified Wed Feb 13 15:16:41 2008 (GMT) gpg]

First pass at examining uniformity of pi+ signal in the EC by looking at the UVW inner and outer strip numbers for the 2.6r data. The plots below represent the number of hits in each event for the different EC views. A tared, gzipped archive is at the bottom of this page.

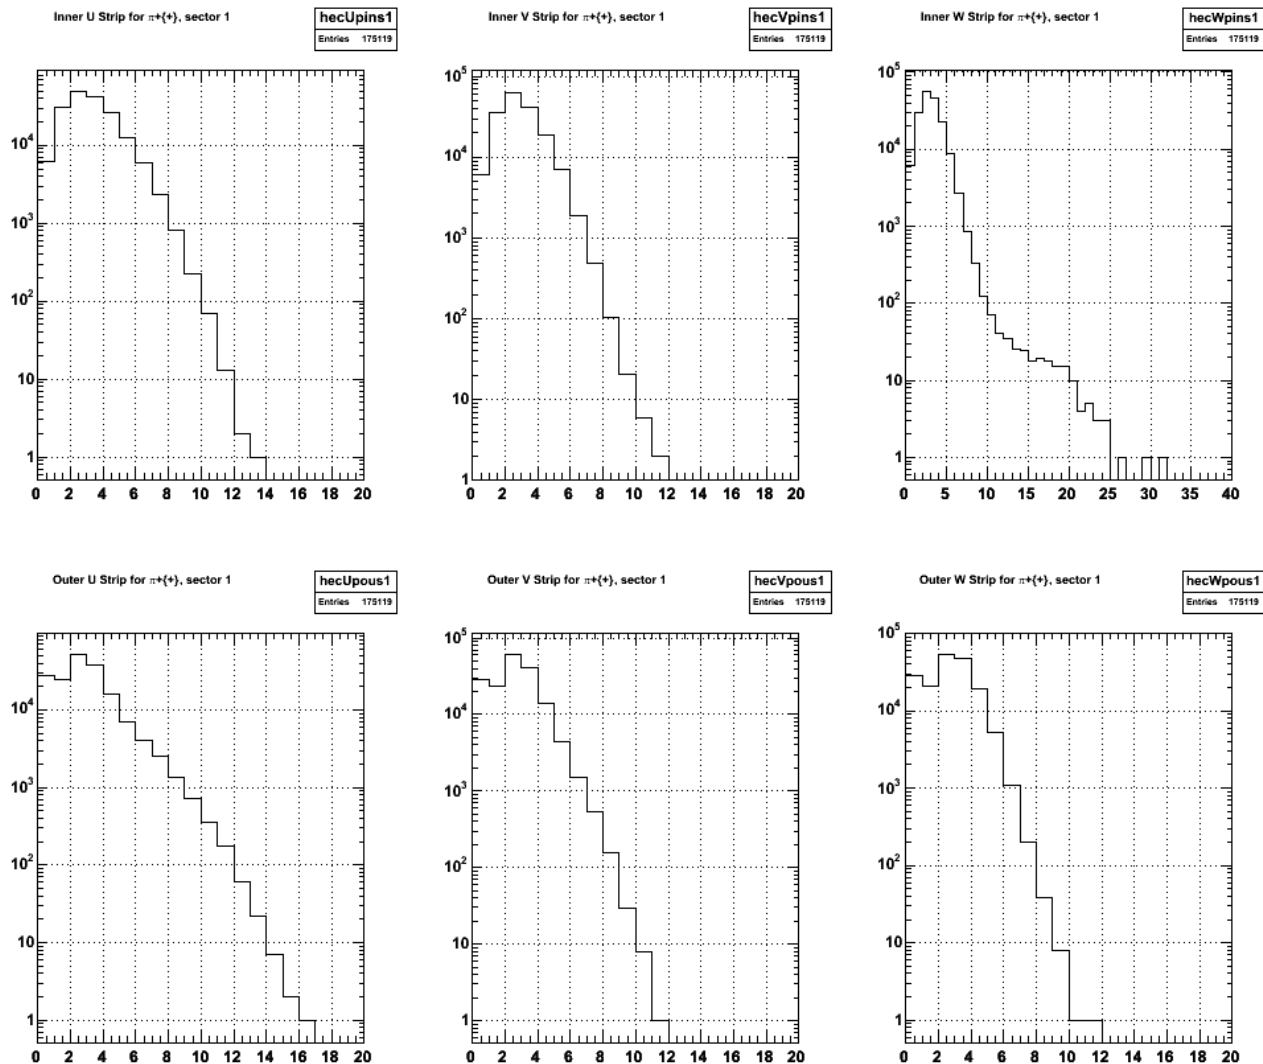

Fig 1. Sector 1, UVW strip numbers for inner and outer EC.

Click [here](#) to view the object (ROOT CINT file for fig 1) you uploaded.

Click [here](#) to view the object (ROOT histogram file for fig 1) you uploaded.

To focus on minimum ionizing particles, we require that the number of hits in each view for both the inner and outer parts of the EC be less than or equal to one. The U plot is shown below. We are dominated by the spikes, but there is still some events spread across multiple strips that we want to get rid of.

2006-12-19 17:35:48

Jerry Gilfoyle's Enotebook page 144 - Question 9 (gpg)

[Modified Fri Jan 5 18:00:24 2007 (GMT) gpg]

9) EC neutron efficiency is obtained separately for each "superpixel" (12 scintillator strips) while in SC for each separate scintillator paddle. Can the averaging over 12 strips in EC wash out single paddle problems? How did you check this?

We looked at the distribution of π^+ 's in the EC which are used to tag the neutrons in the neutron detection efficiency measurement. If the pion efficiency is uniform across the EC, then we expect the efficiency of the neutrons will also be uniform. The first plot below shows the U distribution for positive pions at 2.6 GeV with reversed torus polarity. We required that all events have no more than one strip firing for each EC view (U, V, or W) to focus on minimum ionizing particles. As a result all of the events in Fig 1 are single-pixel EC events. Since the shower from each π^+ is concentrated in a single strip we cannot extract an average position along the width of the strip so the center of the strip is chosen for this position. We can still extract the position along the length of the strip, i.e., along the U, V, or W axis. This single-pixel effect creates the sharp peaks in the red histogram in Fig 1. Notice that there are twice as many of the sharp, red spikes as there are strips (see below for more). There should be 36 strips so we rebinned the histogram so that pairs of the sharp, red spikes were summed together to get a better view of the EC performance as a function of strip.

2007-01-05 11:09:13

Figure 1. Histogram of the U signal in sector 1 for single-pixel events for 2.6 GeV, reversed polarity.

The results for each sector and each view is shown in Figure 2-4.

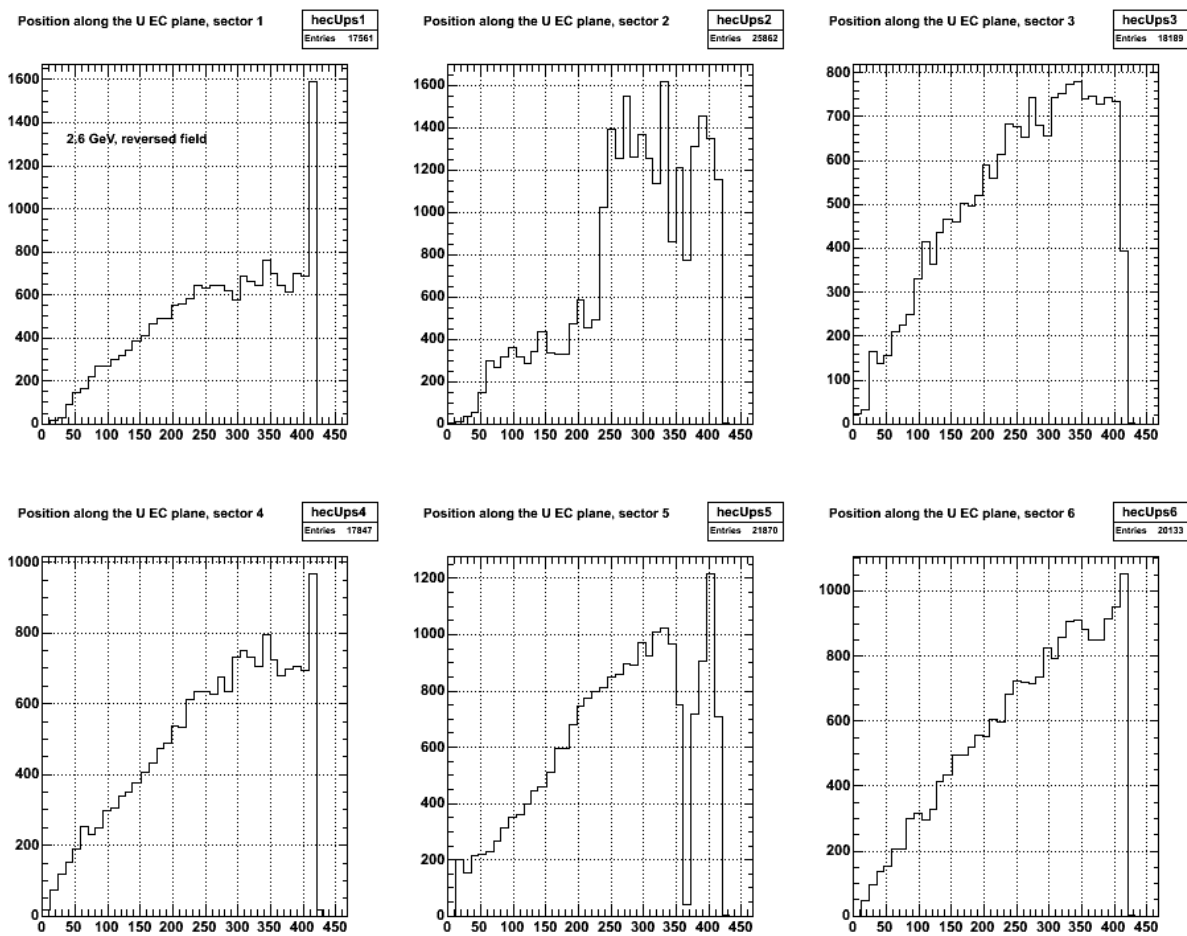

Fig 2. U spectra for single pixel events, 2.6 GeV, reversed polarity.

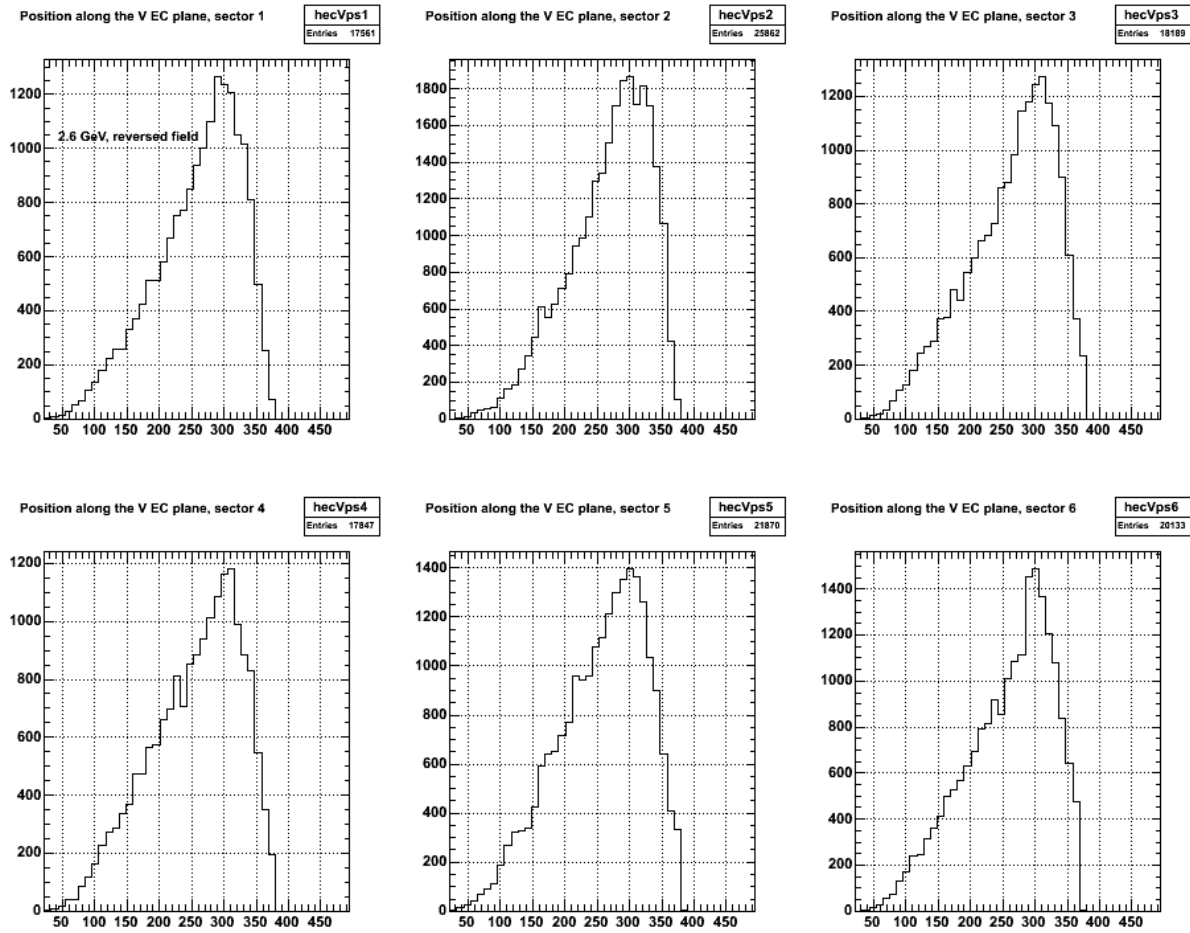

Fig 3. V spectra for single pixel events, 2.6 GeV, reversed polarity.

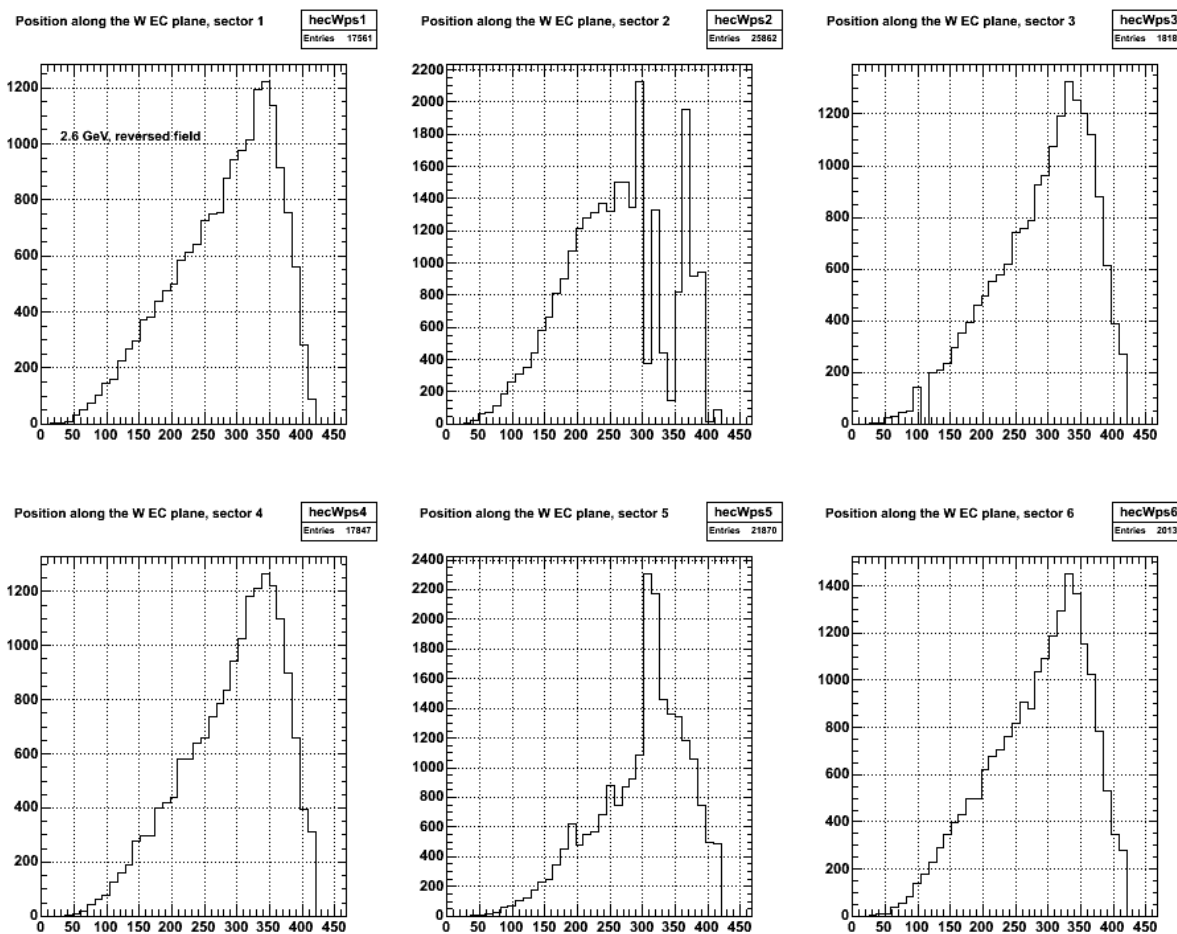

Fig 4. W spectra for single pixel events, 2.6 GeV, reversed polarity.

The U, V, and W spectra for the 2.6-GeV, reversed field data are shown below in Figure 5 summed over all sectors.

Fig 5. Plot of U, V, and W spectra summed over sectors for 2.6 GeV, reversed polarity data.

To explain the double peaks for each strip seen in Figure 1 consider the schematic diagram below of the face of the EC. It shows part of a single U strip, a single V strip, and two adjacent W strips (the black lines). The red, dashed lines are the center lines of each strip. Two EC pixels are labeled 1 (light blue) and 2

(green). For a single-pixel event in pixel 1, we will obtain some position along the red, dashed center lines in each view. Most of the events will be in the upper half of the triangular pixel simply because that half has a larger area and solid angle. The purple (magenta) lines drawn in pixel 1 show the approximate range of values we obtain for this pixel. The ranges for each view form the purple triangle inside pixel 1. Averaging over these distributions will give us a value in the upper half of the pixel and the strip.

Consider now pixel 2 (in green). Following a similar argument, the ranges of values for each strip are shown in the blue, inverted triangle. Now, when we extract the average position of the hits over these ranges, we will obtain a value in the lower half of the pixel and the strip. We will see two peaks for each strip corresponding to the different orientations of the adjacent pixels.

Fig 6. Schematic drawing of a portion of the face of the EC showing how the U, V, and W strips for pixels.

The high-resolution U, V, and W spectra are shown in Figures 7-9

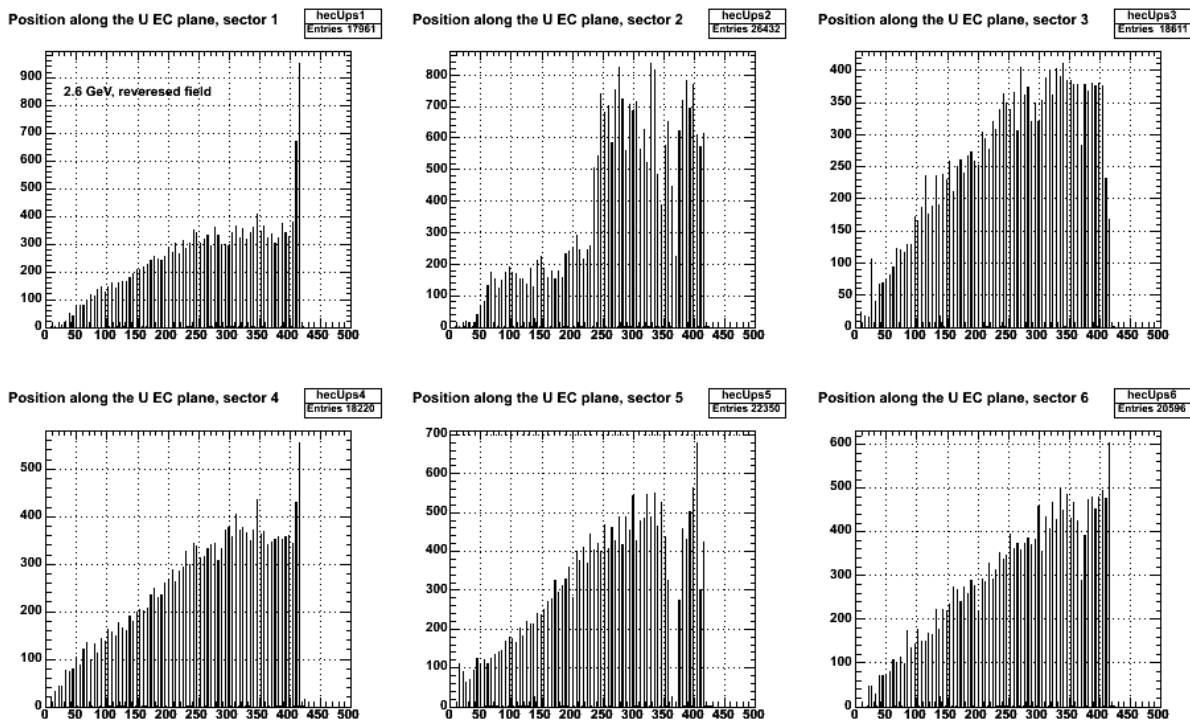

Fig 7. U spectra by sector. Cuts: 1 or fewer hits for all strips, 2.6r.

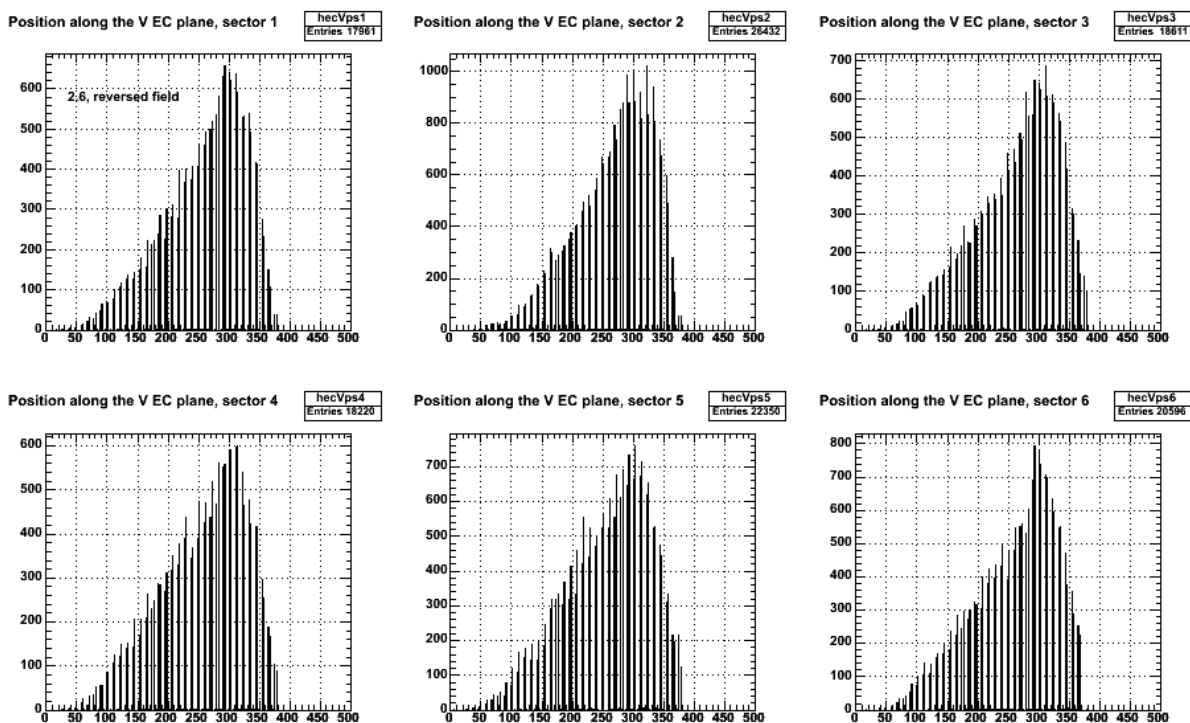

Fig 8. V spectra by sector. Cuts: 1 or fewer hits for all strips, 2.6r.

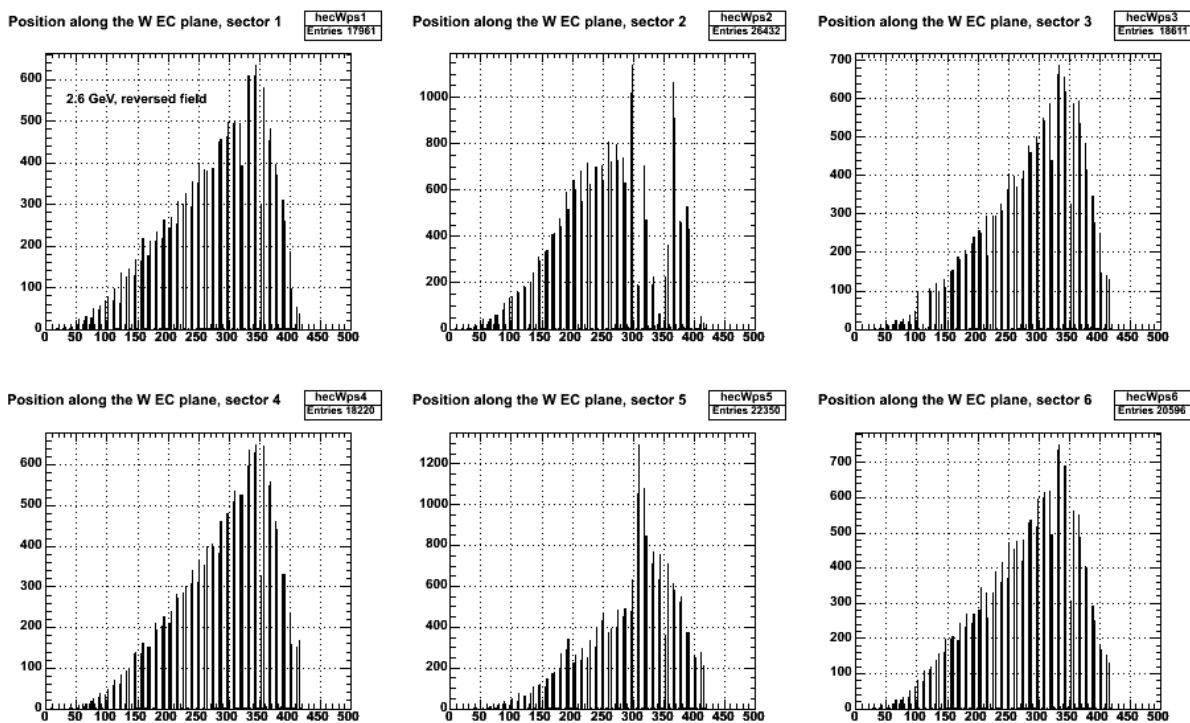

Fig 9. W spectra by sector. Cuts: 1 or fewer hits for all strips, no EC outer signal, 2.6r.

Jerry Gilfoyle's Enotebook page 147 - more calculations from Sabine (gpg)

[Modified Mon Feb 12 21:41:00 2007 (GMT) gpg]

This is the latest calculation from Sabine. It looks less like the data than her previous calculation. The solid, green, curve is averaged over the Q^2 distribution for the 2.6r data. The dashed, green curve is for $Q^2=1.1$ GeV².

Fig 1. Comparison of different calculations with the 2.6n data. The black curve is a Q^2 -averaged Arenhoevel calculation, the red one is the Sabine calculation for $Q^2=1.1$ GeV² from the fall, 2006 DNP meeting, the solid, green curve is the recent (2/07), Q^2 -averaged from Sabine, and the green, dashed curve is the recent (2/07) one for $Q^2=1.1$ GeV² from Sabine.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

email from SJ after asking why the big change. see entry [317 in E5 elog](#).

Hello Jerry,

It's good to hear from you! Your first question has an easy answer: my Q^2 is positive, while Bill's Q^2 is negative. He just likes to use this definition...

The second question - what changed? - has also an answer - it's the NN amplitude parametrization. I have included some of my comments on this from my previous e-mail below. We could talk on the phone this week, too. Today and tomorrow don't work at all, but Wednesday afternoon (after 3pm) and Thursday would be ok. Just let me know.

Cheers,
Sabine

The main difference between the different calculations are the different NN parameters I used as input for my code, to calculate the final state interactions. The results I sent you earlier were obtained using an average of the $T = 1$ GeV NN parameters obtained from proton-nucleus Glauber scattering. However, your highest Q^2 actually leads to $T = 0.8$ GeV, so I have now adjusted these parameters to match your kinematics. I think/hope that I warned you about this fact a while ago. If you look at the plot called atlpqsql5.ps, you can see the difference between three parametrizations. Two of them are based on proton-nucleus Glauber analyses, one on a phase shift analysis. The Glauber analysis ignored the double spin flip terms in the NN amplitude, and it is reasonable to assume that some of the double spin-flip effects are "absorbed" into the fitted parameters. As I also ignore the double spin-flip terms in my code, I think the Glauber parameters are more consistent. The phase shift analysis includes all NN amplitudes, also the double spin-flips. I still only use the central and spin-orbit part in my calculations, so I'm somewhat philosophically inconsistent doing so. Using the phase shift analysis NN parameters seems to lead to a much lower (slightly negative) result for larger missing momenta.

So, why do I not simply use just the Glauber version of the NN parameters? Well, that doesn't seem to exist for the low energies of your kinematics...So, why don't I include the double spin-flip terms to consistently use all parts of the NN amplitude from the phase shift analysis? That's the right thing to do, I'll work on it, it will take me a little while.

Jerry Gilfoyle's Enotebook page 148 - final response to question 9 (gpg)

[Modified Fri Feb 9 15:44:17 2007 (GMT) gpg]

9) EC neutron efficiency is obtained separately for each "superpixel" (12 scintillator strips) while in SC for each separate stinillator paddle. Can the averaging over 12 strips in EC wash out single paddle problems? How did you check this?

We looked at the distribution of π^+ 's in the EC which are used to tag the neutrons in the neutron detection efficiency measurement. If the pion efficiency is uniform across the EC, then we expect the efficiency of the neutrons will also be uniform. The first three plots below show the U, V, and W distributions for positive pions at 2.6 GeV with reversed torus polarity. The reversed polarity data are better for this comparison because the π^+ 's strike the entire face of the EC. For normal torus polarity settings portions of the EC see very few π^+ 's. We required that all events have no more than one strip firing for each EC view (U, V, or W) to focus on minimum ionizing particles. As a result all of the events in Figs 1-3 are single-pixel EC events which we bin in EC strip number for each view.

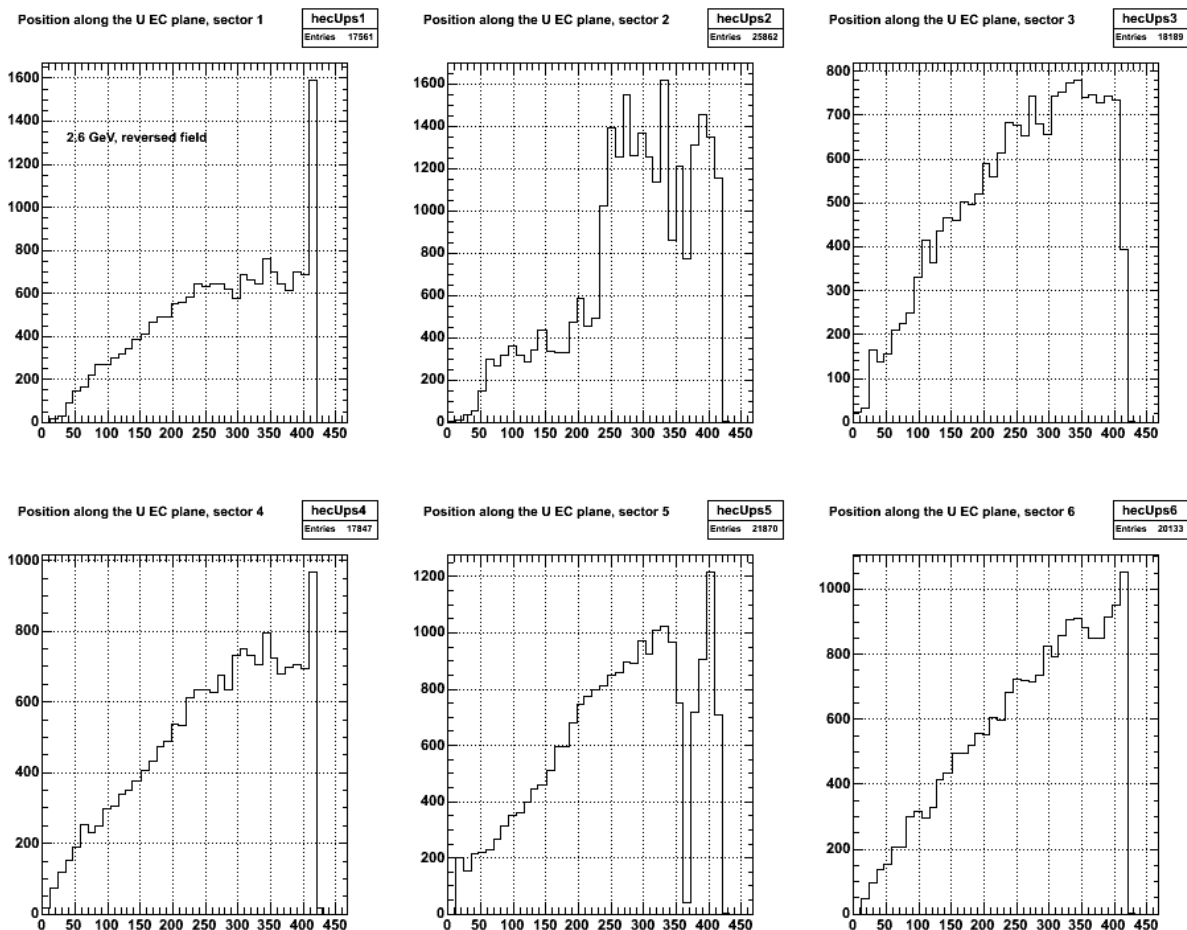

Fig 1. Distribution of counts in the U-view of the EC for single-pixel π^+ events for the 2.6-GeV, reversed torus polarity data.

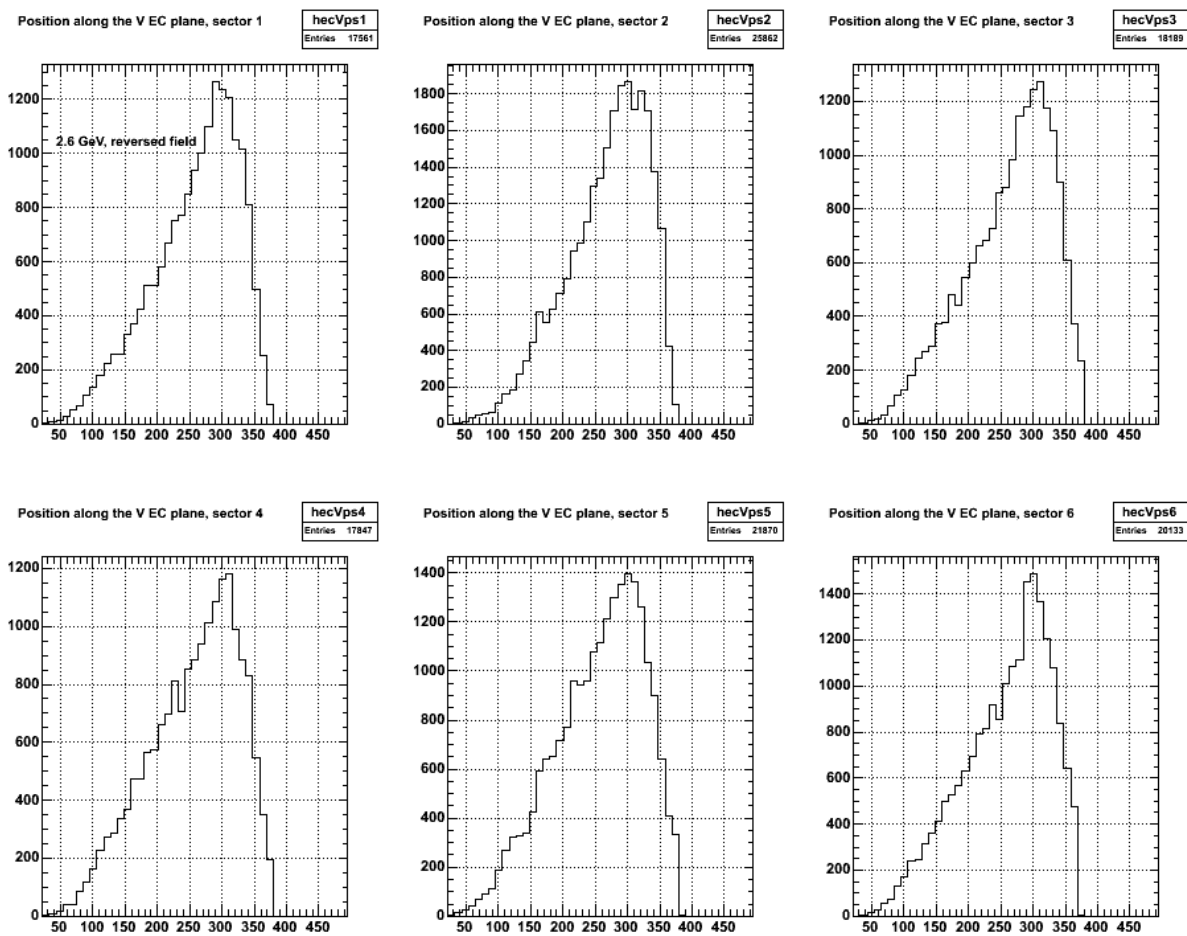

Fig 2. Distribution of counts in the V-view of the EC for single-pixel pi+ events for the 2.6-GeV, reversed torus polarity data.

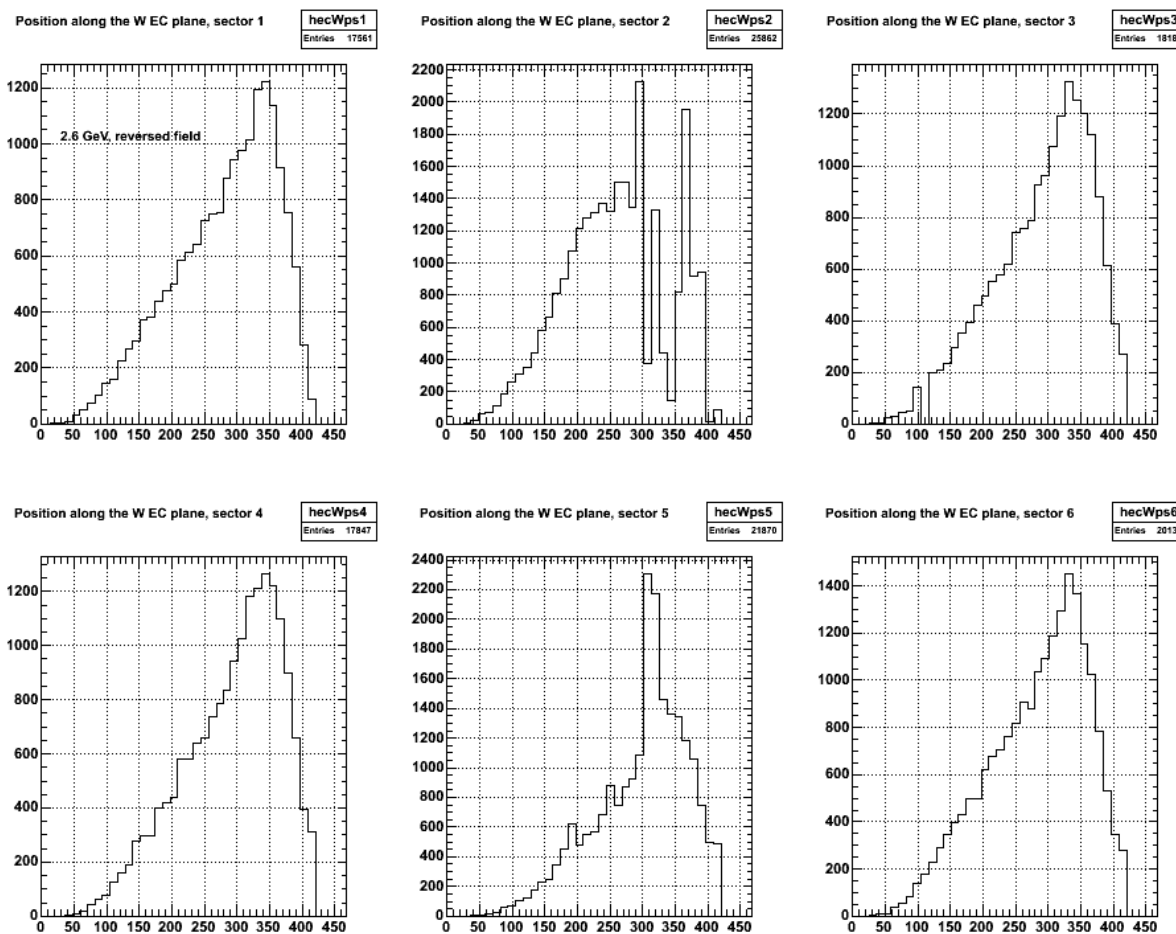

Fig 3. Distribution of counts in the W-view of the EC for single-pixel pi+ events for the 2.6-GeV, reversed torus polarity data.

Figs 1-3 show the count rates for each EC strip in each view and broken down by sector. Some significant variations from sector to sector and strip to strip can be seen. For example, sector 2 in Figure 3 (W view) shows 'holes' (low-efficiency components) among strips in the range 25-30. To test the effect of these inefficiencies on our results, we repeated the extraction of GMn from the 4.2-GeV data excluding sector 2 from the analysis. The results are shown in Figure 4. Leaving sector 2 out has little effect on GMn.

Fig 4. Neutron magnetic form factor extracted with sector 2 excluded.

To make a more global test of the effect of inefficiencies on GMn we excluded all super-pixels whose efficiencies varied by more than 10% from the average for the sector as a whole. The results are shown in Figure 5. Again there is little effect on GMn.

Fig 5. Neutron magnetic form factor extracted without super-pixels whose efficiency varied by more than 10% from the value for the entire sector.

Click [here](#) to view the object (ROOT macro for figs 11-12) you uploaded.

Things above look weird. It turns out I had a parameter set in the genevD input file so that there was a minimum energy transfer (ω) of 25% of the beam energy. This created some weird kinematic constraints that disappeared when I mad that constraint small (1%). See the results below. The number of events that gets through FASTMC is now much smaller.

```
run my ROOT on node 0 for FASTMC ntuple analysis.

hfile3.cd()
hW->SetLineColor(1);
hW->Draw("same")

```

Turn off the Fermi smearing and the W spectrum looks qualitatively correct, but the E' spectrum still looks screwy even after I lowered the minimum angle in QUEEG.

2007-03-05 19:11:25

Fig 3. W spectrum with Fermi smearing turned off.

The problem with the E' spectrum was that there were 'hidden' restrictions on the angular range of the proton and neutron cross section arrays that were used to generate the electron angles. When I lowered those from 10 deg to 5 deg things look much better. See figures below. The Fermi motion is turned off for the inelastic events, but is still on for the quasi-elastic events.

2007-03-06 11:31:36

Fig 4. E' spectrum with lower minimum angle for proton and neutron cross section arrays.

2007-03-06 11:35:40

Fig 5. W spectrum with lower minimum angle for proton and neutron cross section arrays.

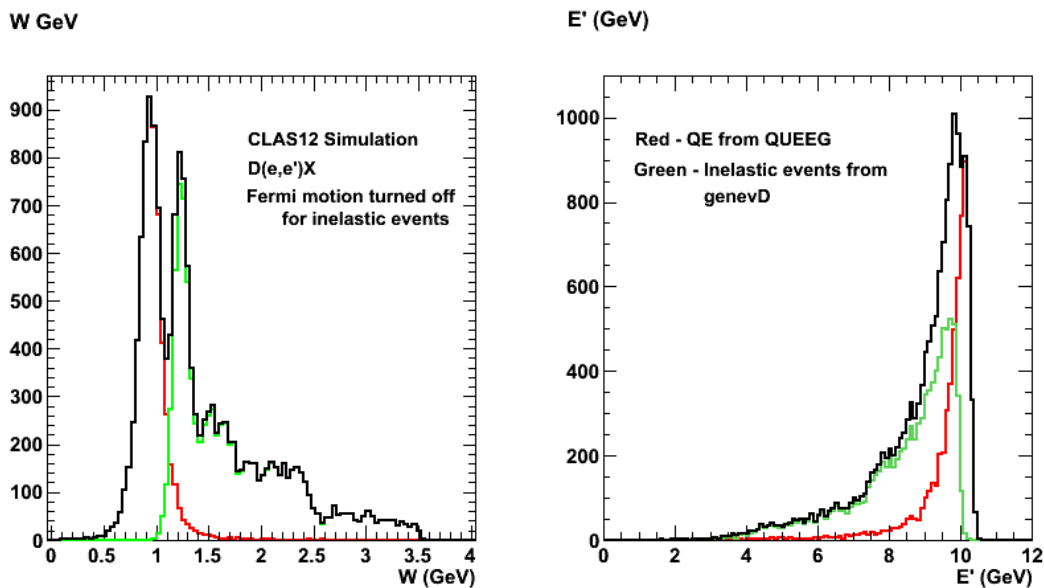

Fig 6. Pretty version of previous two plots.

Click [here](#) to view the object (Compressed archive of histograms for Figs 4-6) you uploaded.

Turn on the Fermi motion. The W spectrum is not peaking at the delta, but at a smaller W . Is this normal?

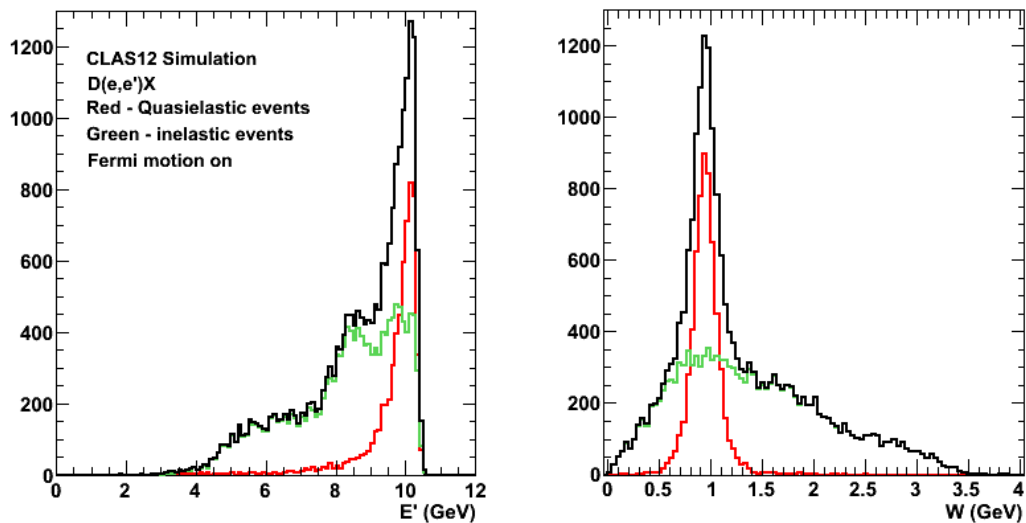

Fig 7. W and E' spectra with Fermi motion turned on.

Click [here](#) to view the object (Archive of histogram files for Fig 7) you uploaded.

Set the THE and PHI angles in the call to LUROBO to zero and get the following. There is little change which may be good news.

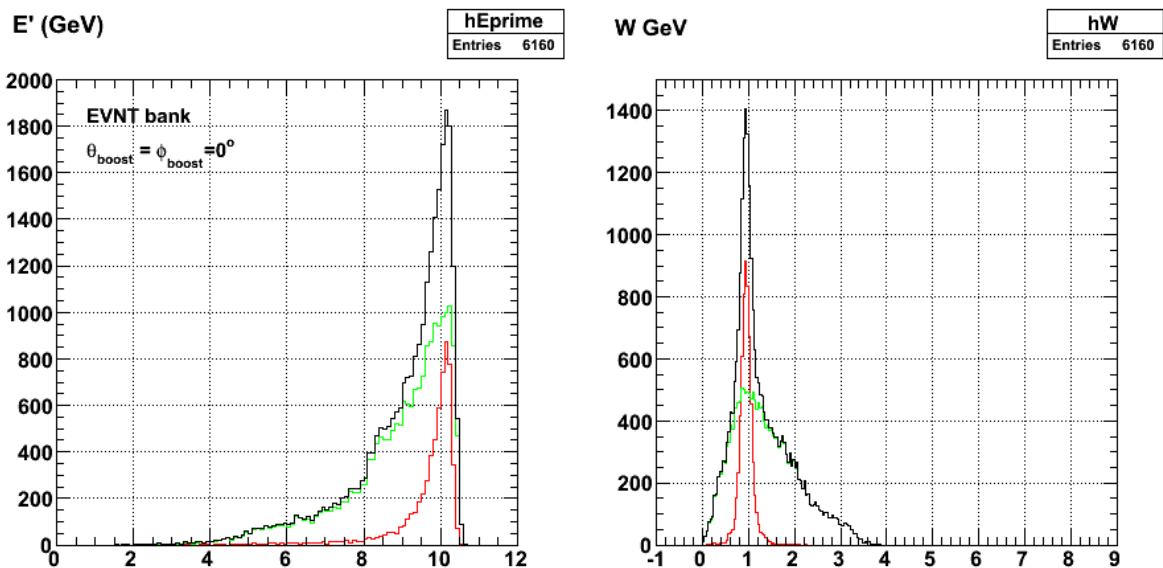

Fig 8. W and E' spectra with Fermi motion turned on, but the rotation angles in the boost (call to LUROBO) are set to zero.

Click [here](#) to view the object (Archive for Fig 8) you uploaded.

The PART bank results are shown below. The peak in the inelastic events is back at 1.3 GeV or so. This means that FASTMC really does a number on the inelastic kinematics!

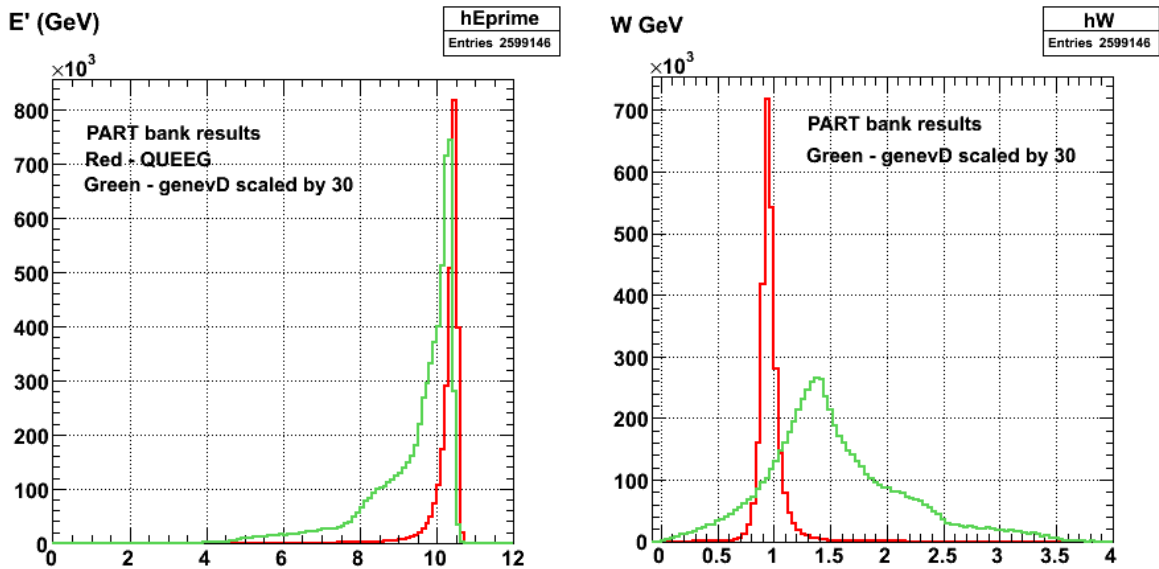

Fig 9. Same as Fig 8 for PART bank.

Lower the beam energy to 4.2 GeV so we can compare the simulations with the E5 data. The results are shown in Fig 10. The inelastic spectrum seems WORSE?! It should have become more narrow, but it looks just as crappy as before or even worse. The quasielastic events look narrower which is what is supposed to happen.

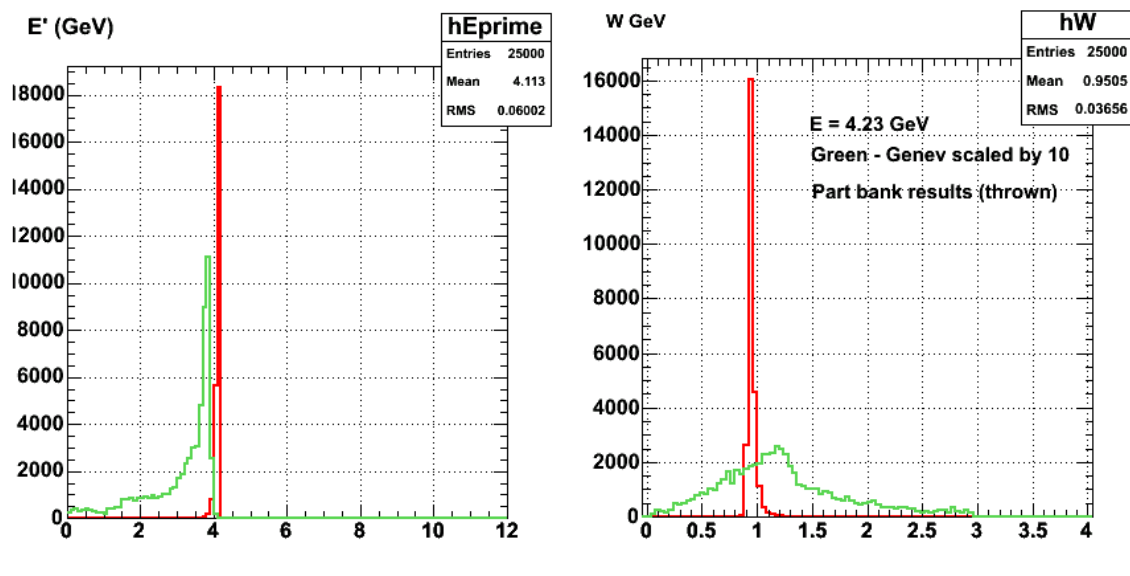

Fig 10. W and E' spectra with Fermi motion turned on, PART bank, and E=4.23 GeV beam energy, but the rotation angles in the boost (call to LUROBO) are set to zero.

Click [here](#) to view the object (Archive for fig 10.) you uploaded.

The above W distribution looks crappy. For the thrown events put in all the standard electron selection cuts and get the following results which looks much better.

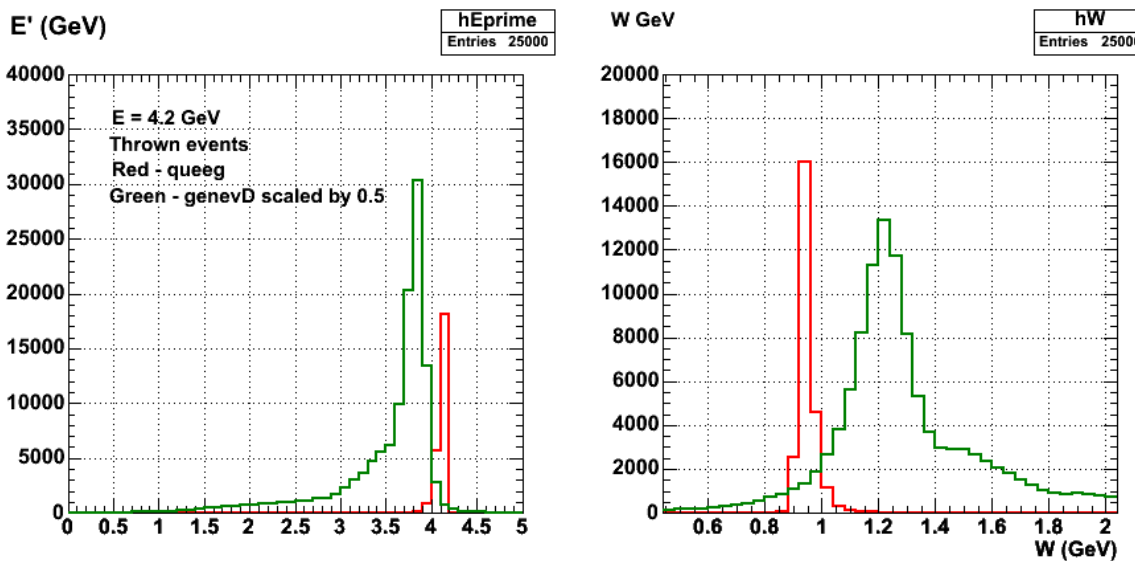

Fig 11. W and E' spectra with Fermi motion turned on, PART bank, and E=4.23 GeV beam energy, but the rotation angles in the boost (call to LUROBO) are set to zero.

Next, put a minimum $Q^2=0.5$ GeV² requirement. Things should get a wee bit wider. They get much worse.

2007-03-11 15:33:08
Fig 12. Same as Fig 11, with a threshold on Q2. This degrades the W spectrum considerably??!

Click [here](#) to view the object (Archive for Fig 12) you uploaded.

Turn off the fermi motion and things look fine. So its the fermi motion simulation that is just killing things.

2007-03-11 15:53:02
Fig 13. Same as fig 12 with Fermi motion turned off.

Click [here](#) to view the object (Archive for fig 13) you uploaded.

Click [here](#) to view the object (input file for Fig 14.) you uploaded.

After much programing of genevD, get the following.

Fig 15. W spectrum after major changes to genevD. With $Q^2 > 0.25 \text{ GeV}^2$.

Click [here](#) to view the object (Archive for fig 15) you uploaded.

The plot above shows the effect of the Fermi motion is smaller than I expected. I've gone from the effect being too large to being too small. I increased the size of the momentum kick in genevD by a factor of 10 to see if there is a discernible effect to make sure that things are not turned off. They are NOT! See the next figure.

2007-03-14 10:40:02

Fig 16. W spectrum after major changes to genevD and multiplying the fermi momentum by a factor of 10. With $Q^2 > 0.25 \text{ GeV}^2$.

Click [here](#) to view the object (Archive for Fig 16.) you uploaded.

Another test. Turn off the Fermi motion by setting the beta vector components to zero and leave everything else the same. The W spectrum does get more narrow so maybe I am doing this right.

2007-03-14 11:00:27

Fig 17. W spectrum after major changes to genevD and turning the Fermi motion off. With $Q^2 > 0.25 \text{ GeV}^2$.

Click [here](#) to view the object (Archive for fig 17) you uploaded.

One of the expectations is that the width of the W distribution for each final state will get larger as Q^2 increases. The plot below shows the separate W distributions for quasi-elastic and inelastic final states for different Q^2 ranges. Each distribution's width seems to increase with Q^2 . I will run this longer with more statistics to nail it down. The calculation is 'normal' (Fermi motion turned on with the accepted Hulthen distribution for the nucleon momentum). The 2D plot shows the Q^2 dependence of W for the summed distribution.

Fig 18. Q2 dependence of W spectra. The inelastic (blue) distributions are scaled to fit on the plot.

Jerry Gilfoyle's Enotebook page 153 - GMn12 angular distributions (gpg)

[Modified Tue Mar 6 19:05:56 2007 (GMT) gpg]

Now look at some of the angular distributions. The first figure compares the thrown (PART bank) and accepted (EVNT bank) angular distributions. The very interesting thing here is the phi_pq-dependence of the inelastic events. They peak at phi_pq = +/- 180 deg leaving a large region in phi_pq with low background. If this holds up it will help a lot getting rid of the inelastic background. This is with Fermi motion turned on, but with THE=PHI=0 in LUROBO.

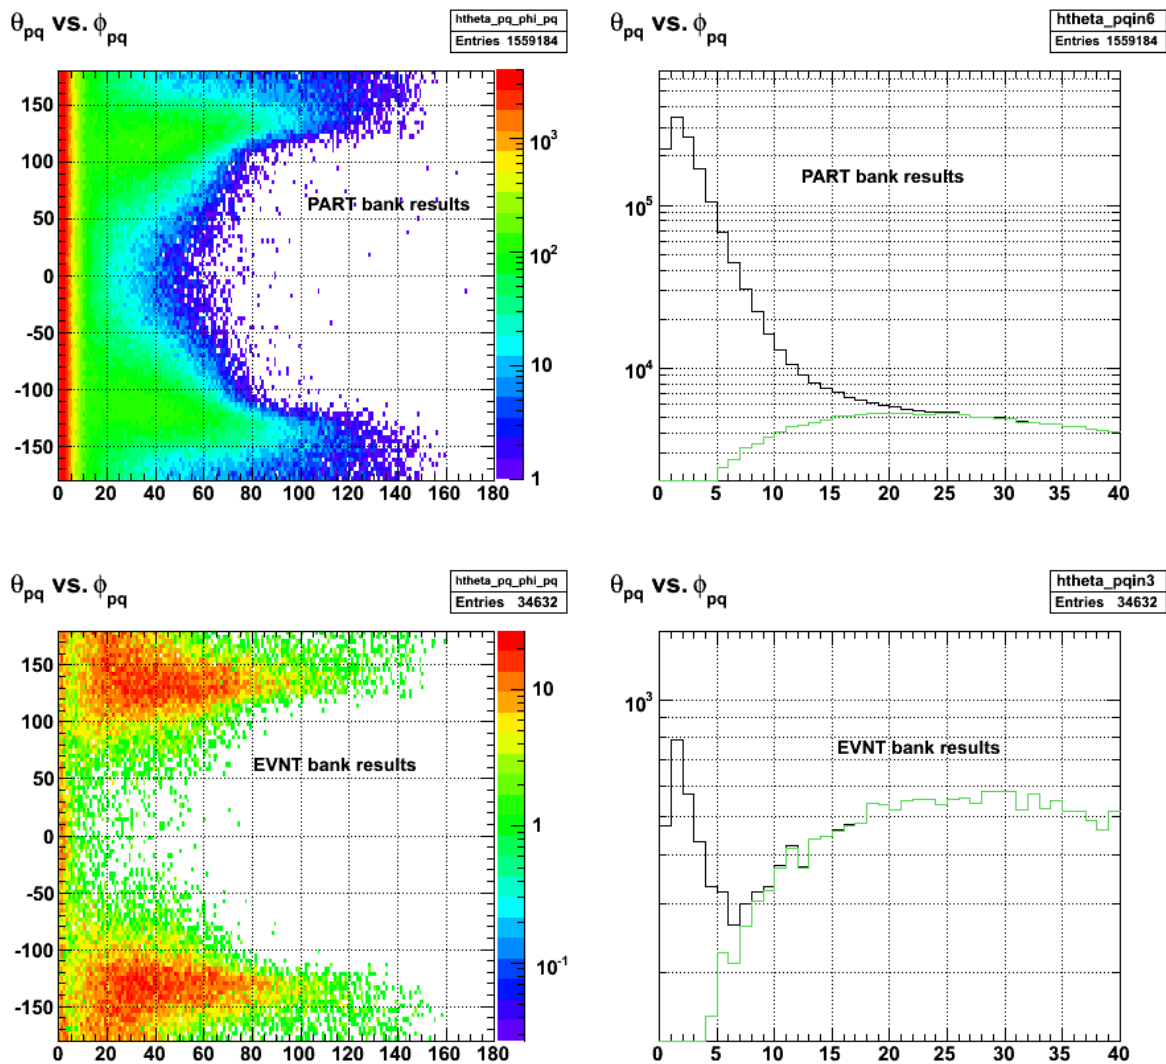

Fig 1. Comparison of thrown and accepted angular distributions.

Click [here](#) to view the object (Archive for fig 1.) you uploaded.

Jerry Gilfoyle's Enotebook page 154 - Relationship between p_m and $\theta_{cm_{pq}}$ (gpg)

[Added Wed Mar 7 16:23:08 2007 (GMT) gpg]

The calculations that we have from Arenhoevel are functions of $\theta_{cm_{pq}}$, but it is sometimes useful to plot his results as a function of the missing momentum, p_m . The relationship between $\theta_{cm_{pq}}$ and p_m is described in a paper by Sabine Jeschonnek and others (Phys. Rev. C 66, 044003 (2002)). A summary of the relationship is shown in the figures below. The first table is a list of definitions of the kinematic variables. The next two figures display the equations needed to relate $\theta_{cm_{pq}}$ to p_m and vice versa.

Figure 1. Definitions of kinematic variables.

Figure 2. Equations for calculation. The masses m_1 and m_2 are the masses of the proton and neutron and m is the average of those masses.

Figure 3. Expression used for W here.

One can also see the relationship between p_m and θ_{cm_pq} in the data. The figure below is one such example for $Q^2=0.8-0.9$ GeV² and $x_{BJ} = 0.95-1.05$ (Bjorken x). The width of the distribution at high p_m and θ_{cm_pq} is due to the finite bin size. The black and brown curves show the upper and lower limits of θ_{cm_pq} at a given value of p_m for this Q^2 and x_{BJ} bin. They nicely mark the limits of the spread in the data. At low θ_{cm_pq} the distribution in p_m extends to higher p_m than one can account for from the finite bin size in Q^2 and x_{BJ} . For $\theta_{cm_pq}=0$ this width reflects the longitudinal momentum of the 'spectator' neutron in the deuteron when the virtual photon strikes the proton.

**Figure 4. $\theta_{cm_pq}^{cm}$ vs. p_m**

We expect that the helicity asymmetry ALT_p should go to zero at $\theta_{cm_pq}=0$ and $p_m=0$. Some recent results show some significant deviations from this expectation. See entry [190](#). If we look at the same distribution shown in Figure 4, but expanded about $p_m=0$ and $\theta_{cm_pq}=0$ we get the following results. At θ_{cm_pq} there are very few events and these are likely due to events shifted down in θ_{cm_pq} due to the resolution of CLAS.

**Figure 5. Expanded view of θ_{cm_pq} vs. p_m near the origin.**

Jerry Gilfoyle's Enotebook page 155 - Plots for CAN - MM vs. theta_pq (gpg)

Jerry Gilfoyle's Enotebook page 158 - GMn12sim (gpg)

[Modified Fri Mar 16 04:12:21 2007 (GMT) gpg]

In preparation for submitting a proposal to the next PAC for beam time to measure GMn at 12 GeV, we have been developing a simulation to study data rates, predict uncertainties, and test the proposed analysis techniques. The simulation builds as much as possible on existing software and consists of two main pieces.

1. Simulation of the quasi-elastic scattering off protons and neutrons in deuterium. This is a modified (slightly) version of Jeff's QUEEG program. Since it uses the Galster parameterization for the cross section, there appears to be no inherent problem with performing the calculation at higher energies and Q2. The modifications have been to make the angular limits in the code consistent with CLAS12 (e.g., minimum scattered electron angle). QUEEG12 already has a model of the Fermi motion of the nucleons.
2. Simulation of the inelastic events with the GENEV program originally from the Genova group. This code was written to study electroproduction of (among other things) pions from a proton target via delta and higher-W resonances. These events form the background beneath the quasi-elastic peak that is the main focus of the GMn measurement. According to Raffaella DeVita, there appears to be no serious problems with running the code at higher energy, except the Q2 dependence of some of the pion production channels is not correct. The code does not include the Fermi motion of the nucleons in deuterium. This is a significant drawback so we have spent the last few weeks putting in a model of the Fermi motion into GENEV. We call the modified code genevD. Our approach is analogous to what Jeff used in QUEEG though the implementation is different. We follow these steps to simulate the Fermi motion.
 1. The nucleon momentum inside the deuteron is chosen from the Hulthen distribution shown in Figure 1 below. The direction is taken randomly in the azimuthal angle phi and in the cosine of the polar angle theta. This last step leaves out an important effect. The 'effective' energy of the beam on the struck nucleon is higher or lower depending on the direction of the Fermi motion. Nucleons moving toward the incoming beam see a higher energy. Nucleons moving away from the beam see a lower energy. The cross section depends on the beam energy and we are, at the moment, ignoring this effect. We would like to come up with a parameterization of the inelastic cross section as a function of the energy transfer nu and the scattering angle theta or a parameterization of the delta cross section since much of the background under the quasi-elastic peak will come from the delta. There is a Brasse parameterization for delta production off the proton (F.W.Brasse et. al., Nucl. Phys. B110, 413 (1976)), but apparently nothing on the neutron.

Fig 1. Distribution of nucleon momentum inside the deuteron.

2. Once we have the Fermi momentum vector, we boost the electron beam 4-momentum to the nucleon rest frame using a routine called LUROBO in the JETSET library. We then rotate the frame of the boosted electron so the beam 3-momentum vector lies along the z axis. In this nucleon rest frame we calculate the incoming electron energy.
 3. The code then proceeds as usual, but with a different 'beam' energy for each event. It generates 4-momenta for the scattered electron, nucleon, and pion and photons (in the case of the pi0). The data are stored in a COMMON block (yes, it's in FORTRAN) that is accessible to the JETSET routines.
 4. We then reverse the procedure in part A above. We perform the reverse rotation of the nucleon rest frame and make the opposite boost using the routine LUROBO again. The routine performs the boost on all the particles in the event.
 5. At the end we are left with the scattered electron, nucleon, pion, and photons in the lab frame.
3. Running each code is controlled from a Perl script. The user has to decide how many events of each type (quasi-elastic or inelastic) is wanted.

To test the effect of the Fermi motion we did some calculations at 4.2 GeV so that we can compare them with our observations of the E5 data. The plots below show the results for the thrown events. The accepted events are those that make it through the FASTMC program for CLAS12. Figure 2 shows the W distribution at 4.2 GeV for the quasi-elastic and inelastic events. The relative number of events in each region is an arbitrary choice here. The Q2 range is for all Q2 > 0.25 GeV2. The quasi-elastic peak is narrow. The delta peak is clearly visible along with higher-W events. There is a small overlap between the two regions.

2007-03-14 10:36:35

Fig 2. Separate W spectra for thrown events at 4.2 GeV for quasi-elastic and inelastic events.

Figure 3 shows the same spectra as Figure 2, but now with the Fermi motion turned off for the inelastic events only. The delta peak is more narrow and even the limited overlap with the quasi-elastic peak has been reduced.

2007-03-14 11:00:27

Fig 3. Same as Figure 2, but with the Fermi motion turned off for the inelastic events only.

We expect that as Q^2 increases the effect of the Fermi motion will grow. To test our code we did a new calculation with a different quasi-elastic-inelastic ratio and looked at the W spectra in a series of Q^2 bins. The results are shown in Figure 4. The overlap between the two regions gradually increases as Q^2 goes up.

W spectra for thrown events at 4.2 GeV and Fermi motion turned on. Each panel corresponds to a different Q² range.

Jerry Gilfoyle's Enotebook page 159 - Parameterization of the Inelastic Cross Section (gpg)

[Modified Thu May 3 20:38:45 2007 (GMT) gpg]

Note: See revisions to weighting functions starting below fig 7 below. See entry [343](#) in the E5 logbook for the latest versions.

In the last week, we have unearthed a couple of ways to parameterize the inelastic cross section for the $p(e,e')X$ reaction. One is by Brasse, et al., (Nucl. Phys. B110 413 (1976)) and the other is by Paul Stoler (Phys. Rev. D 44, 73 (1991)). The Brasse, et al. one is not well-suited to our purposes, because it cuts off at $W=1.1$ GeV and where the cross section is still not zero. We would like to get the inelastic cross section as low in W as possible where it forms the background under the quasielastic peak. The Stoler parameterization is shown in figure 1.

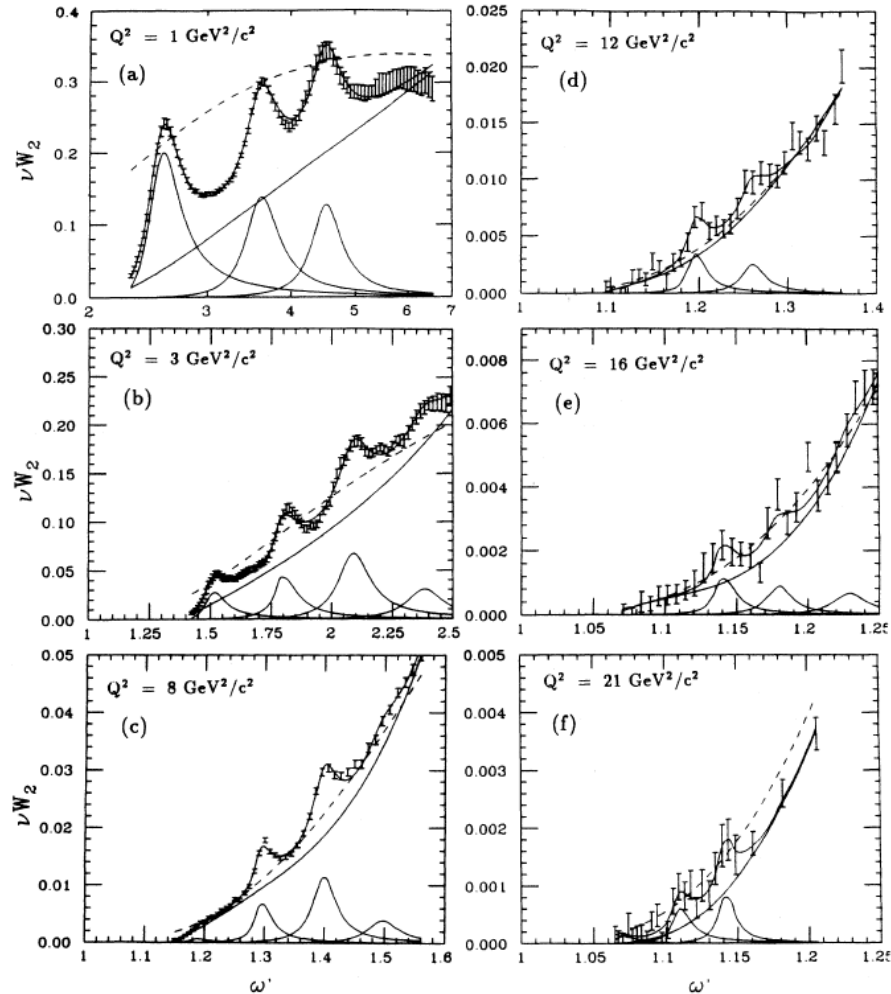

FIG. 1. Examples of spectra of inclusive (e, e') data as a function of ω' , where $\omega' = \omega + M^2/Q^2$. M is the nucleon mass and $\omega = 2M\nu/Q^2$. (a) and (b): the data were reconstructed from parameters in Ref. [18] (c)–(f): SLAC data from Refs. [14]–[17]. The solid curves are the result of least-squares fits to the data. The lower curves are the contributions from the individual resonances. The dashed curves are the extrapolation of the data from the scaling region using an empirical relation given in Ref. [3].

Figure 1. Figure from Stoler article.

He assumes the longitudinal part of the cross section is zero and then fits a set of resonances plus background to the data (largely taken at SLAC). The resonant fit parameters are shown in the table below taken from a review article by him (Phys. Reports 226 103 (1993)).

Figure 2. Table taken from Stoler review article.

The parameters for the non-resonant background are apparently not available until Paul can find out where the Department VAX is now. I talked to him about this and we can just read the points off the figure and regenerate the curves.

Mon Apr 9 09:28:48 2007

Fig 3. Distribution of effective beam energies due to Fermi motion in the deuteron from genevD.

Click [here](#) to view the object (ROOT macro for fig 3) you uploaded.

Click [here](#) to view the object (input file for fig 3) you uploaded.

The plot above shows the distribution of effective beam energies in genevD for Ebeam=11 GeV when cos(thetaN) and p_fermi (the Fermi momentum and direction of the nucleon) are chosen at random. I need the integral from the inelastic cross section parameterization over the range Ebeam +/- 3*sigma or 8.9 - 13.1 GeV. The range of the integral was W2: 0.05->2.5 GeV, theta: 7-40 degs. See the results below.

Entrance Channel Weighting Function

Mon Apr 9 11:04:15 2007

Fig 4. Effective energy dependence of the weighting function.

Click [here](#) to view the object (Mathematica notebook used to generate integrals used in Fig 4.) you uploaded.

EEkkk!!! I left out the sin(theta) factor when I did the integrals for the previous plot. The corrected plot, ROOT macro, and Mathematica notebook are below.

Entrance Channel Weighting Function

Thu Apr 12 18:12:29 2007

Fig 5. Effective energy dependence of the weighting function with corrected integration.

Click [here](#) to view the object (Mathematica notebook for Fig 5) you uploaded.

Click [here](#) to view the object (ROOT macro for fig 5) you uploaded.

The next step is to get the effective beam energy as a function of momentum and polar angle of the Fermi momentum of the nucleon inside the deuteron. That function is shown in the left panel of the figure below where the surface is a function of p_{fermi} taken from the Hulthen distribution and $\cos(\theta)$ where θ is the polar angle of the moving nucleon. For each point in this surface, we then calculate the weight using the fitted curve from the figure above.

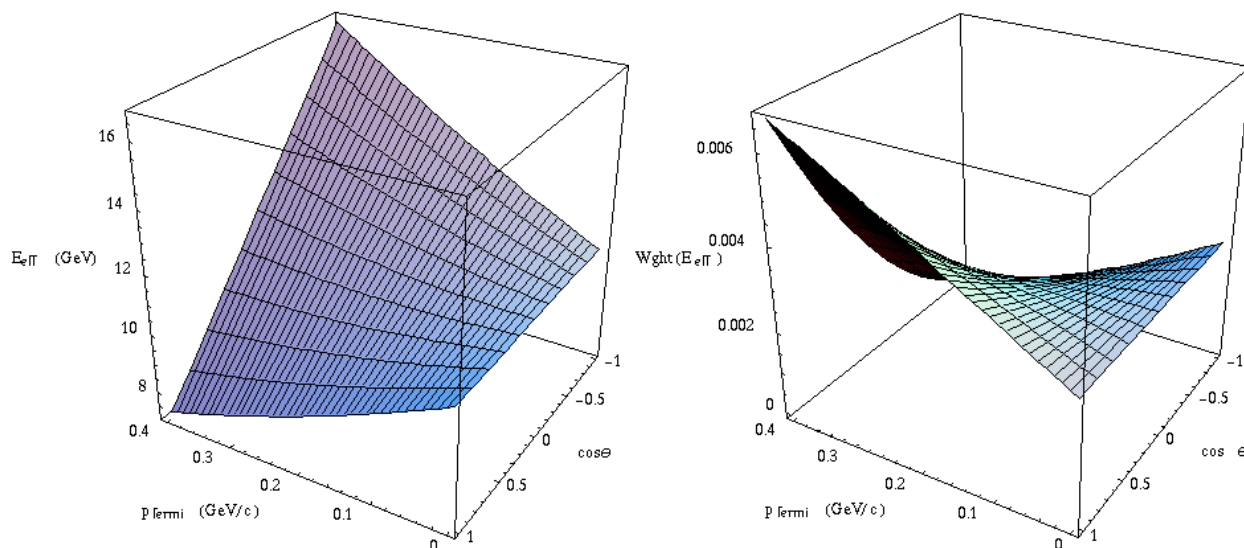

Fig 6. The left panel shows the dependence of the effective beam energy as a function of the magnitude of the Fermi momentum p_{fermi} and $\cos(\theta)$ where θ is the polar angle of the moving nucleon. The right panel shows the dependence of the weight function taken from the previous figure also as a function of p_{fermi} and $\cos(\theta)$.

The right panel in the previous figure is the weight associated with the variation of the cross section with the effective beam energy. We still need to include the effect of the distribution of momenta due to the Fermi motion of the nucleon. We do that by multiplying the weight in the right panel of the previous figure by the Hulthen distribution and obtain the following.

Fig 7. Weighting function for the Fermi motion.

This function is now incorporated into genevD. To choose the Fermi momentum and direction we pick three numbers at random; (1) The Fermi momentum is chosen in the range 0-0.4 GeV/c, (2) $\cos(\theta)$ is chosen in the range -1 to 1, and (3) a weight is chosen in the range from zero to the maximum of the weight function in Figure 7. If this random weight is less than the weight function at that value of p_{fermi} and $\cos(\theta)$, then p_{fermi} and $\cos(\theta)$ are kept and the code continues. If the random weight is greater than the weight function, that triple (p_{fermi} , $\cos(\theta)$, and the random weight) is thrown out and another three random numbers are chosen. The process is repeated until we get an acceptable choice of p_{fermi} and $\cos(\theta)$.

The weight function is calculated in genevD with a Fortran, CERNLIB function called FINT. A grid of points representing the weighting function is stored in several arrays and the CERNLIB function interpolates to find the value of the surface. This has been coded into genevD and we are testing things now. One of the tests we have done is to compare the weighting function calculated with FINT and one calculated with Mathematica using the same grid of points. The results are shown in the table below. For most of the points, Mathematica and FINT are in close agreement (much less than 1%, but there are two points in the table where the difference grows to 1.5%. At the moment, we don't think this is very serious. The test was done with an earlier version of the calculation so the actual values of the weighting function have changed, but the agreement between FINT and Mathematica is encouraging.

FINT	Mathematica	delta	(delta/ave)*100
882.90979	882.035	0.87479	0.0991
5495.36084	5473.02	22.3408	0.4074
306.636047	305.635	1.00107	0.3270
9134.56445	9127.83	6.73445	0.0738
12692.9258	12887.2	-194.27	-1.519
11662.8789	11665.3	-2.4211	-0.021
4581.19385	4575.57	5.62385	0.1228
5014.6333	4937.21	77.4233	1.5560
6258.04395	6238.09	19.9540	0.3194

There were several problems associated with the analysis above of the weighting function. The plot below shows a revised weighting function versus the effective beam energy. The cos(theta) is not quite the one we want for the CLAS12 acceptance.

Fig 8. Revised entrance-channel weighting function. Compare with fig 4.

Jerry Gilfoyle's Enotebook page 161 - QE-inelastic ratio (gpg)

[Modified Wed May 9 16:21:37 2007 (GMT) gpg]

We need to set the ratio of quasielastic to inelastic events in the GMn@12GeV simulation. Here we will use the data to guide us. We will get the ratio from the 4.2-GeV, E5 data with $Q^2 > 2.0$ GeV². The Q^2 cut is used to make the kinematic range more like what is available in the simulation. We have inelastic data down to $Q^2 = 1.0$ GeV², but there could be problems due to the entrance-channel, effective-energy effect created by the Fermi motion in the simulation.

2007-05-01 09:10:09

Fig 1. W2 spectrum of he 4.2 GeV electron singles events with no Q2 cut.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Fig 7. Effect of $\theta_{pq} < 3.5$ deg cut on W2 spectrum. Yukkk!

Click [here](#) to view the object (ROOT histogram file for fig 7) you uploaded.

Set $\theta_{pq_cut}=2$ deg.

Fig 8. !!!!!

Click [here](#) to view the object (ROOT macro for fig 8) you uploaded.

The problem above was created by bugs in the Perl scripts that were not deleting old files and properly replacing them with new ones.

The plots below show the W2 spectrum and theta_pq distribution at 11 GeV. We had expected that the W2 QE peak would get wider, but this effect is extreme! At the same time we expected the theta_pq angular distribution to be more narrowly focused at small angles which is exactly what we see here.

Fig 9. W2 spectrum for Q2=12-14 GeV2 for both QE and IN simulations. The IN simulations (green curve) have the Fermi motion turned off.

Click [here](#) to view the object (ROOT macro for fig 9.) you uploaded.

2007-05-09 12:19:20

Fig 10. Angular distribution of theta_pq for QE and IN events. The Fermi motion has been turned off in the IN events (green curve), but the Fermi motion is still on in the QE events (red curve).

Jerry Gilfoyle's Enotebook page 162 - QE selection (gpg)

[Modified Thu May 10 13:32:27 2007 (GMT) gpg]

Study of selecting QE events at 12 GeV. The decay channels chosen for genevD are the following.
 C 2) $V_{\text{Gamma}} + P \rightarrow P + \text{P}10$

Fig1 shows the effect of the theta_pq cut on the W2 spectrum for e-p coincidences. The QE peak sits under a vary large background, but the theta-pq cut chops down a huge amount of the inelastic cross section.

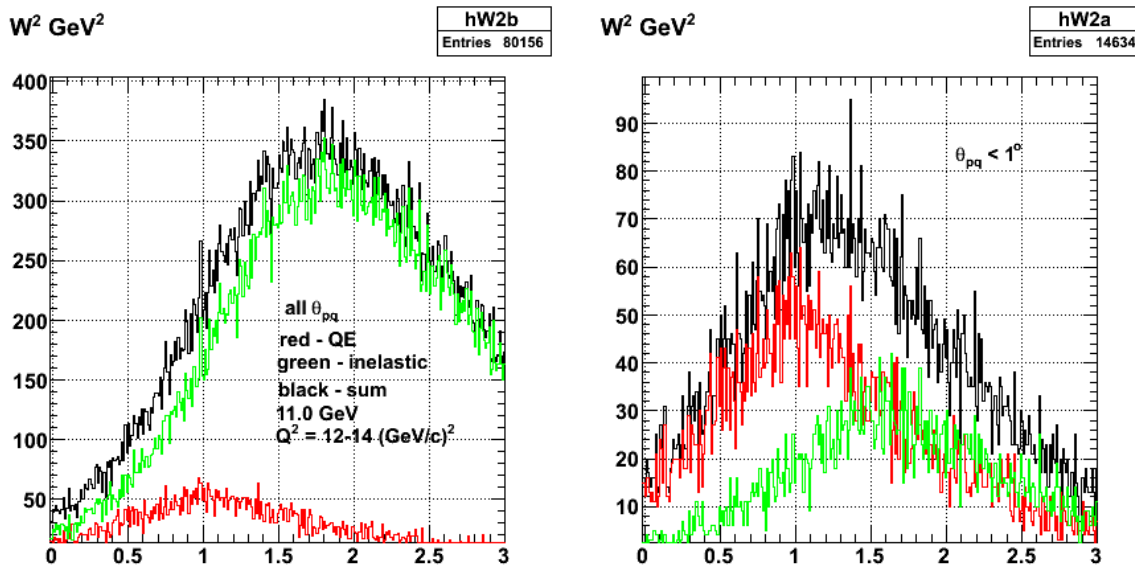

Fig 1. Comparison of W2 spectra with (right) and without (left) the theta_pq cut for 11-GeV, Q2=12-14 GeV2.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (tar archive of ROOT files for fig 1) you uploaded.

Fig 1 is for eD->epX events. Now try limiting them to just eD->epn events.

Fig 2. Angular distribution of theta_pq for QE, inelastic, and QE+inelastic.

Click [here](#) to view the object (ROOT macro for fig 2) you uploaded.

Fig 3. Missing mass spectrum for ep events.

Now put the mm2, neutron cut on along with the theta_pq cut and things look GOOOD!!!! YEEEEHAAA!!

Fig 4. Results for Q²=12-14 GeV² with various cuts.

Click [here](#) to view the object (ROOT macro for fig 4) you uploaded.

Click [here](#) to view the object (tar archive for fig 4) you uploaded.

Jerry Gilfoyle's Enotebook page 163 - Coplanarity angle (gpg)

[Modified Tue May 15 04:55:58 2007 (GMT) gpg]

Using the coplanarity angle to isolate QE events from inelastic.

2007-05-14 18:59:48

Fig 1. Coplanarity angle distribution for ep events with QE cut turned on.

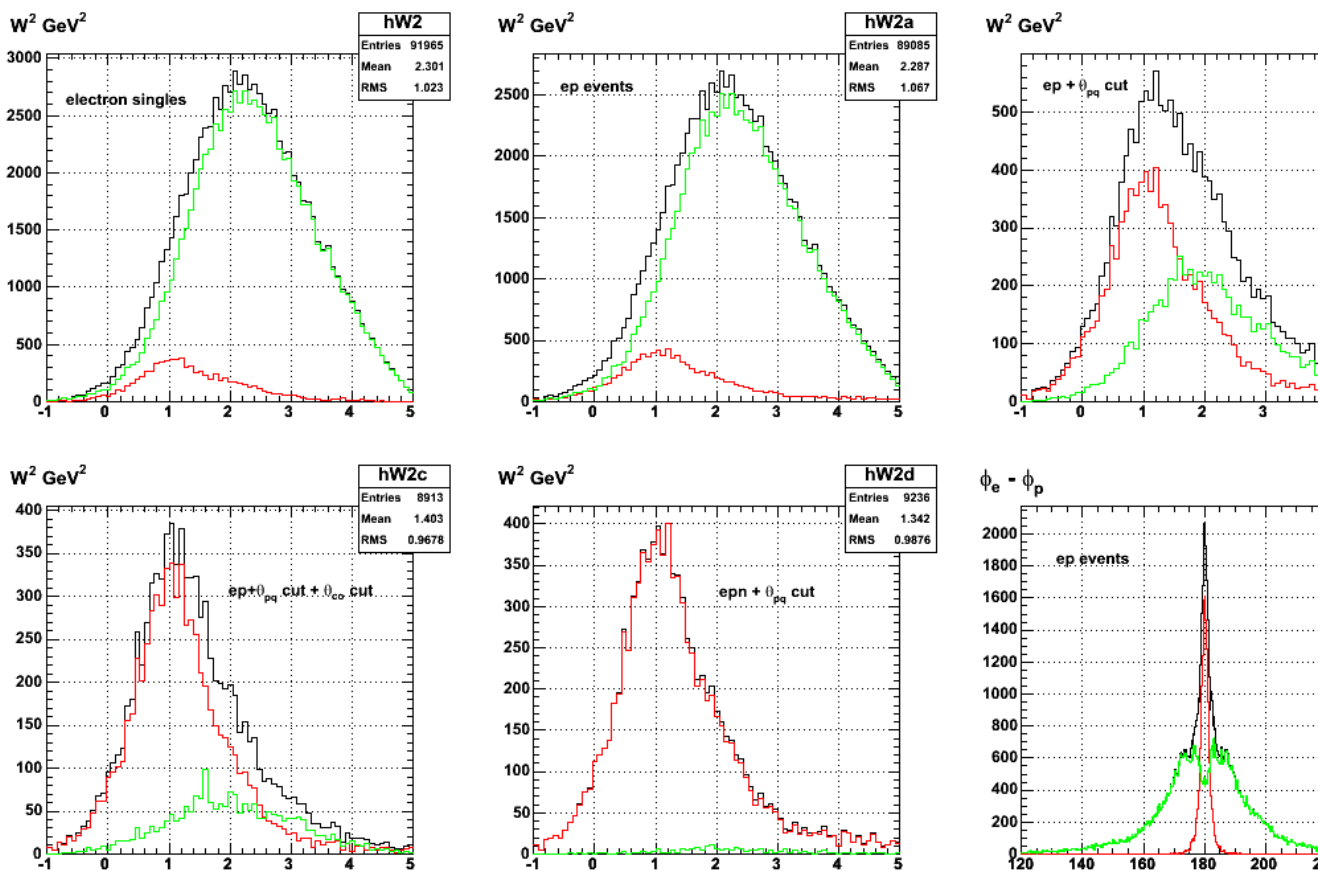

Fig 2. Effect of different cuts on W^2 spectrum. Note the difference between fig 1 and the lower right panel. Something is screwy in fig 1

Jerry Gilfoyle's Enotebook page 164 - Previous W2/E' results (gpg)

[Modified Thu May 17 22:34:49 2007 (GMT) gpg]

Plot below to show what happens to the QE peak at high energy and Q2. The reference is Phys. Rev. Lett., 49, p. 1139 (1982).

FIG. 1. The cross section for e - d scattering at incident energy $E = 15.742$ GeV vs scattered-electron energy E' at 10° . The dashed (dotted) curve is the smeared elastic (inelastic) e - p cross section obtained with method II and the Paris potential (Ref. 9). The solid curve is the result of a linear least-squares fit of the other two curves to the e - d cross section as described in the text. All cross sections are radiatively corrected.

E' distribution at 10 GeV.

Q2	Ebeam
10.0	21.0
8.0	18.5
6.0	15.7
4.0	12.6
2.5	9.8

See next entry for more on this run for W2=6-7 GeV2 and IN/QE=28.

2007-05-17 18:23:08

Fig 2. Our simulation of E' compared with Fig 1 from SLAC.

Click [here](#) to view the object (ROOT macro for fig 2) you uploaded.

2007-05-17 18:33:56

Fig 3. Prettier version of fig 2

Click [here](#) to view the object (ROOT macro fig fig 3) you uploaded.

Jerry Gilfoyle's Enotebook page 165 - More realistic ratios (gpg)

[Modified Wed May 23 03:33:28 2007 (GMT) gpg]

Now try putting in more realistic ratios of IN:QE using the Mathematica notebooks inelasticInputs2.nb and xsec2.nb. The first plot below shows the results for the upper limit $W^2 < 4.0$ GeV² for getting the ratio of IN:QE so the input values are the following submitted to 10 nodes in the cluster.

N(QE) = 5,300
N(IN) = 720,000

Fig 1. Effect of cuts for GMn.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (tar archive for fig 1) you uploaded.

Now in getting the QE:IN ratio integrate over $W^2 < 3.0$ GeV².

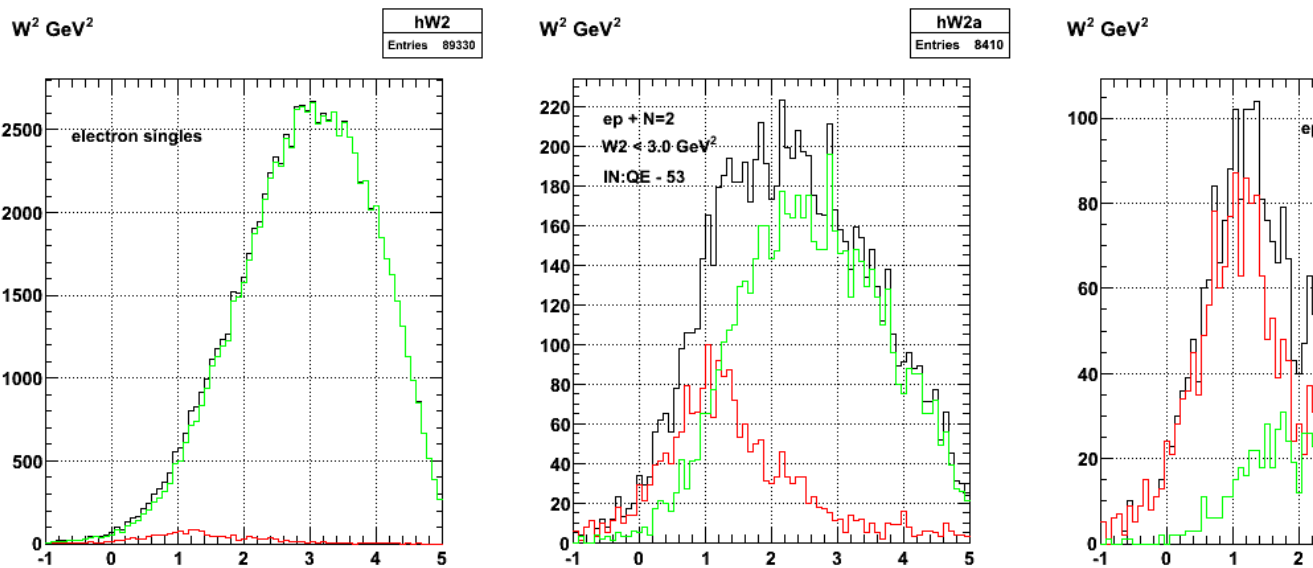

Fig 2. Same as fig 1 with $W^2 < 3$ GeV² in generating the QE:IN ratio.

Click [here](#) to view the object (tar archive for fig 2) you uploaded.

Click [here](#) to view the object (ROOT macro for fig 2) you uploaded.

2007-05-17 16:00:14

Fig 3.

Fig 4.

Fig 5. Effect of coplanarity cut.

Click [here](#) to view the object (ROOT macro for fig 5) you uploaded.

For $Q^2=6-7 \text{ GeV}^2$ we get the following results. I reduced the statistics by a factor of five to get it done sooner and because there is still tons of counts, the command was

```
submit_gmsim.pl 10000 300000 1
```

Fig 6. QE selection for $Q^2=6-7 \text{ GeV}^2$

Click [here](#) to view the object (ROOT macro for fig 6) you uploaded.

Click [here](#) to view the object (tar archive for fig 6) you uploaded.

Fig 7. Replacement for fig 6 because I didn't have the Q2 cut right for the two left-hand panels.

Click [here](#) to view the object (ROOT macro for fig 7 you uploaded).

Click [here](#) to view the object (tar archive for fig 7) you uploaded.

Now I have to think. The 'N=2' cut in fig 7 excluded $ep \rightarrow e'pn$ events and anything with a third particle in the final state beyond the e' . I think this is what I actually want, but below I look at events like that OR if the third particle is a neutron.

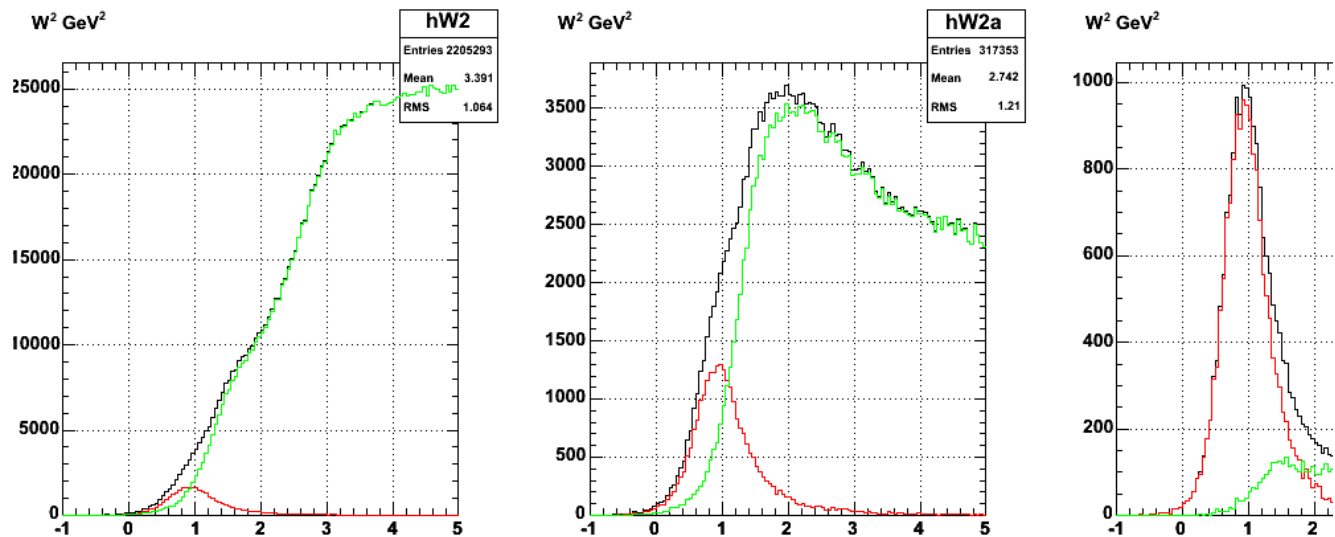

Fig 8. Same as fig 7 but with the addition that the 'N=2' cut now includes 'N=3' events with a neutron to make an epn final state.

Click [here](#) to view the object (ROOT macro for fig 8) you uploaded.

Click [here](#) to view the object (tar archive for fig 8) you uploaded.

Jerry Gilfoyle's Enotebook page 166 - theta_pq effect (gpg)

[Modified Mon May 21 22:09:05 2007 (GMT) gpg]

Study the effect of the theta_pq cut for selecting quasielastic events. Set the theta_pq cut at the last QE bin that is greater than the IN count.

Fig 1. Angular distributions of theta_pq for ep+N=2 events (left panel) and W2 spectrum with theta_pq cut=1.5 deg.

Click [here](#) to view the object (Fig 1. ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (tar archive for fig 1) you uploaded.

2007-05-21 18:07:35

Same as fig 1 with theta_pq < 1 deg.

Jerry Gilfoyle's Enotebook page 168 - Troubles after turning on neutrons (gpg)

[Modified Tue May 29 20:07:53 2007 (GMT) gpg]

The W2 spectra and angular distributions looks much worse now that I have put the neutron code into FASTMC. This is for Q2=6-7 GeV2.

Fig 1. With $ep+N=2+\theta_{pq}$ cuts where $N=2$ is strict (no more than $e+p$ in final state).

2007-05-28 22:36:06
 Fig 2. Same as fig 1, but now $N=2$ is for $e+p+X$ where X could be nothing, pions, etc.

2007-05-28 22:46:38

Fig 3. Multiplicity of events with at least an electron.

Fig 4. Effect of cuts. The N=2 cut is far less effective now for reasons that are mysterious.

Click [here](#) to view the object (ROOT macro for fig 4) you uploaded.

Click [here](#) to view the object (tar archive for fig 4) you uploaded.

I have put the N=2 cut back on so that ep events must have 2 particles and no others. This reduces the inelastic background by about 90% which is consistent with previous results. There is still more inelastic background than before, but that may be caused by the fact that I did not have good control over the true ratio of QE to inelastic. The way to check that ratio is with the thrown events. The number of events for QE and IN chosen at run time can be very different from the proper one because events go down the beam pipe, at too large an angle, ... The bad news is that my previous results had too small a ratio of IN to QE. However, the comparison with the 10 GeV SLAC results seems to imply that even those ratios are conservative.

Fig 5. 11 GeV, IN:QE = 14:1, $W^2 < 3 \text{ GeV}^2$. left - singles, middle - ep+ strict N=2 cut, right - ep + N=2 cut + θ_{pq} cut (1 deg).

The angular resolution for neutrons in the EC is (according to Stepan) about 0.5 deg. Natasha is running GSIM this weekend to get a better idea of what it should be. The theta resolution above is about 1.5 deg which is probably not exactly the right comparison. The 0.5 deg should be the sum in quadrature of the theta and phi resolutions. Assuming they are the same (standard assumption for CLAS12 at this point), then I am getting a resolution of 2.1 deg not 0.5 deg! This would nicely account for the width of the neutron theta_pq distribution. Below is theta_pq for neutrons with the width reduced by a factor of three.

2007-06-02 10:48:24

Jerry Gilfoyle's Enotebook page 173 - Selecting Quasielastic Neutron events at 12 GeV (draft E5 entry) (gpg)

[Modified Sat Jun 2 14:48:24 2007 (GMT) gpg]

One of the requirements for the ratio method is to select quasielastic proton and neutron events. For protons, we have shown there is good separation between the quasielastic events and the inelastic background (see entry 353) using the requirements that θ_{pq} be less than some small angles (about 1 deg for 11 GeV) and that no more than two particles be detected in the final state. This second requirement is an addition to the cuts made for E5. Here we investigate the selection of quasielastic neutron events from the $D(e,e'n)p$ reaction. Events are simulated in the same manner as in entry 353 (QUEEG for quasielastic neutrons and genevD for inelastic events) and the results are shown in Figure 1. The left-hand panel shows the W^2 spectra inclusive electrons for quasielastic only (red), inelastic only (green), and the sum. The quasielastic contribution is small as in the proton case and is largely lost in the background. The middle panel shows the same spectra, but now requiring a neutron in the final state. There is still a very large background under the quasielastic peak. All of the plots below are for $Q^2 = 6-7$ GeV² and a beam energy of 11 GeV.

Fig 1. W^2 distribution for electron singles {left-hand panel}, e-n coincidences {middle panel}, and e-n coincidences with $\theta_{pq} < 1$ deg (right-hand panel). In each plot the red curve represents quasielastic events, the green is the inelastic contribution, and black is the sum.

To reduce the inelastic background in the right-hand panel of Fig 1 we have required that the final state have only the two detected particles (e and n) and no others. These other particles are usually pions or photons from the inelastic reactions. The effect of this cut is shown in Fig 2. It reduces the inelastic background by about a factor of ten.

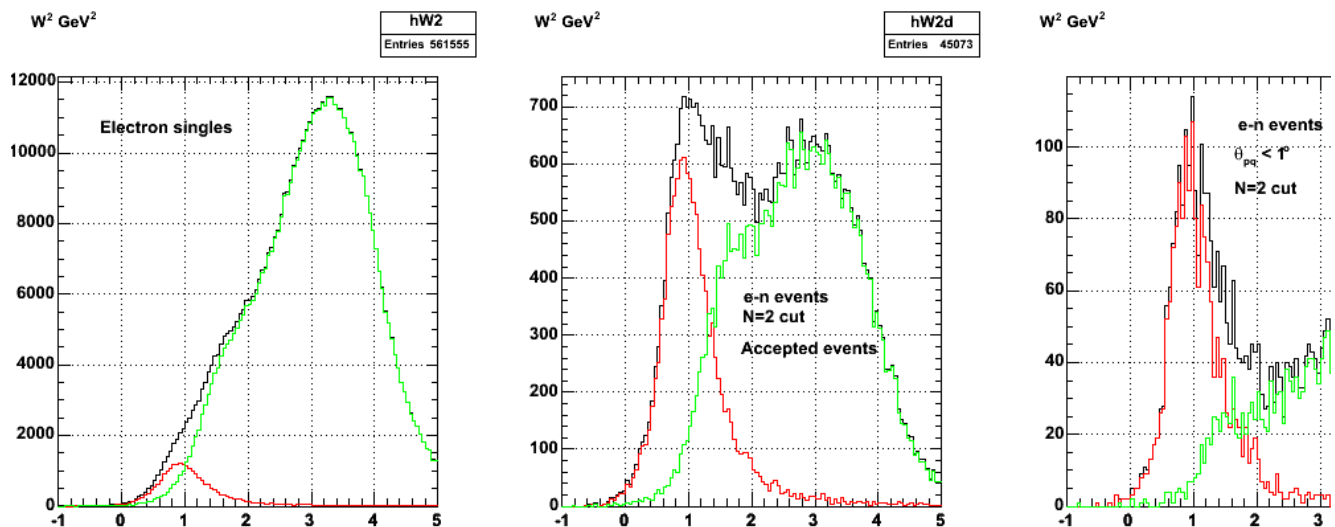

Fig 2. Same as Figure 1 (the right-hand panels are exactly the same) except the middle and left-hand panels also require an electron and neutron in the final state and no other particles (N=2 cut).

Click [here](#) to view the object (ROOT macro for Fig 2.) you uploaded.

Click [here](#) to view the object (tar archive for Fig 2.) you uploaded.

There is however, a concern here. Note that the number of quasielastic events that pass the theta_pq cut is small. Compare the red histograms in the middle and left-hand panels of Figs 1-2. This is due to the fact that the lower angular resolution of the EC has spread out the angular distribution of the quasielastic events and many are now falling outside the cut. This is NOT the case for protons where we can rely on the tracking to get high-resolution angle information. To show this explicitly, we show the angular distribution of theta_pq in Fig 3. The left-hand panel is for accepted events that have passed through the full simulation including FASTMC. The right-hand panel shows quasielastic events that were thrown and do not show the effects of smearing in FASTMC. The smeared, quasielastic angular distribution is much wider. Its peak is at theta_pq=2 deg versus 0.5 deg for the thrown distribution. The 1-deg theta_pq cut used in the analysis for Figs 1-2 was cutting out a large portion of the quasielastic events. To capture the full distribution the theta_pq cut should be more like 4 deg.

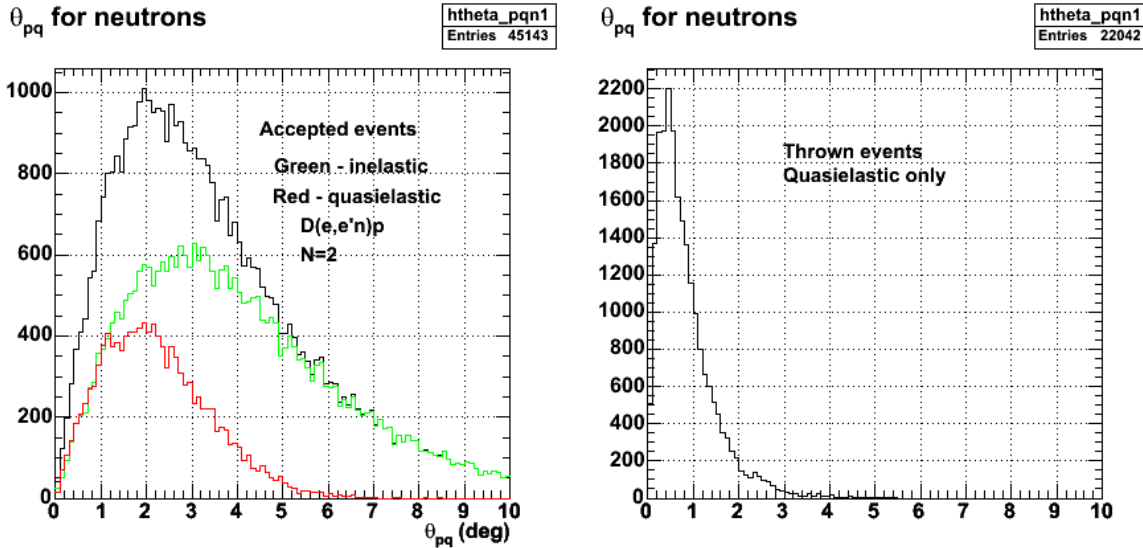

Fig 3. The left-hand panel shows the angular distribution of theta_pq for accepted quasielastic events (red histogram), inelastic (green), and their sum (black). The right-hand panel shows the angular distribution of thrown quasielastic events.

The effect of increasing the theta_pq cut to 4 deg is shown in Fig 4. The histograms are the same as in Fig 2 (the 'N=2' cut is on in Fig 4) except the theta_pq cut has been raised to 4 deg in the right-hand panel.

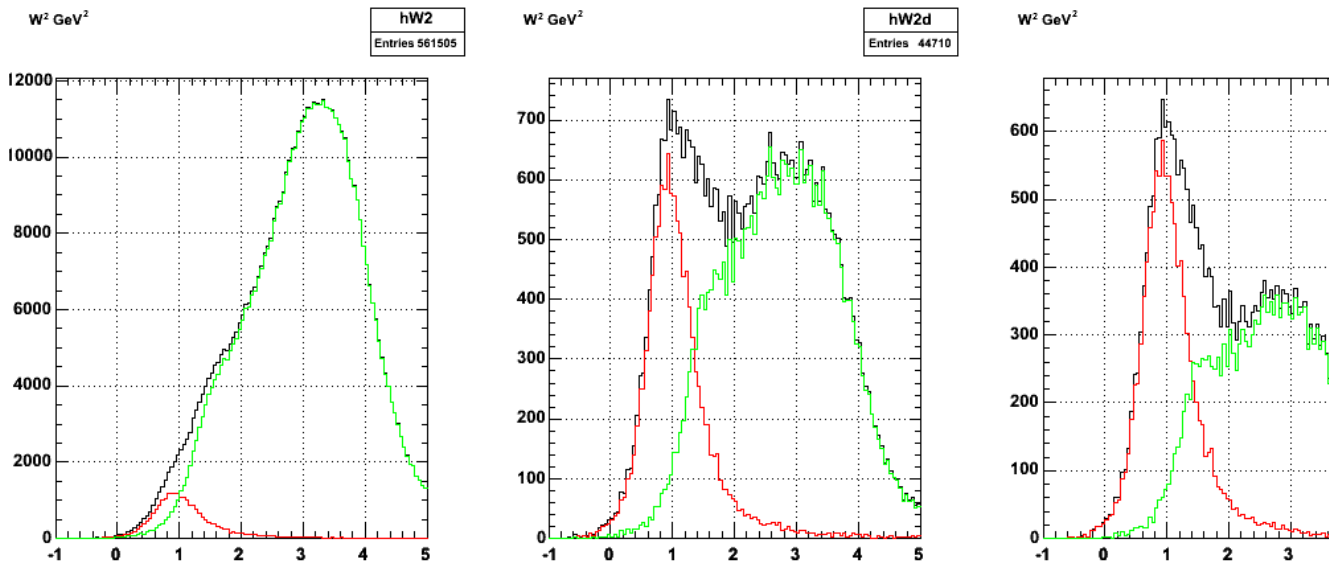

Fig 4. Same as Fig 2 with theta_pq < 4 deg instead of 1 deg.

The effect of a 4-deg theta_pq cut on the selection of quasielastic proton events is shown in Fig 5. Compare these results with entry 353.

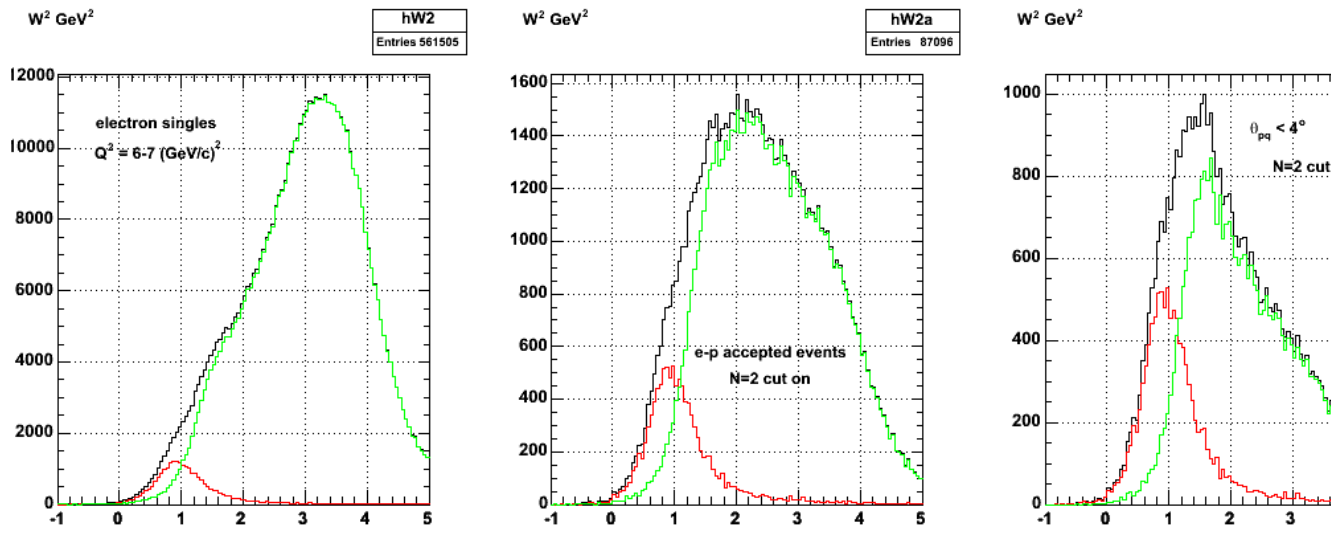

Fig 5. Same as Fig 4 except for protons instead of neutrons.

Jerry Gilfoyle's Enotebook page 177 - Draft of elog entry on systematic uncertainty due to NDE parameterization (gpg)

[Modified Fri Jun 8 03:34:28 2007 (GMT) gpg 1

The uncertainty in the parameterization of the neutron detection efficiency is the largest single source of uncertainty in the GMn measurement. To estimate that uncertainty in the proposal we have done the following.

1. We start with function that will describe the neutron detection efficiency (NDE) at least qualitatively. However, we decided to avoid a simple polynomial because that is the function that was used to fit the NDE in Jeff's thesis since that could bias the result. We chose to use the function

$$\text{nde} = S * (1 - (1 / (1 + \exp((x - r_0) / a))))$$

where S is the plateau in NDE for $p_n > 2$ GeV/c, r_0 is a constant representing the position in p_n of the middle of the increasing portion of the NDE, and a controls the slope of the NDE in the increasing NDE region. The points in Figure 1 fall along this curve.

Fig 1. Monte Carlo simulation of the neutron detection efficiency along with two fits to the simulated data.

2. We use the distribution of measured neutrons as a function of momentum and the assumed NDE function from above to obtain the number of neutrons as a function of momentum. The square root of this number gives us the uncertainty in that neutron momentum bin.
3. Monte Carlo events are thrown in each momentum bin with a Gaussian distribution with the centroid and width from the previous step.
4. We fit the distribution with the original source NDE given above (which simply recovers the original parameters) and with a third-order polynomial in p_n with a plateau (we will refer to this as the JL function). The results are shown in Figure 1. Notice the small differences between the red curve (original source NDE) and the green one (JL curve). We chose the original source function so that it would have the same features as the measured neutron detection efficiency, but would NOT make a perfect fit to the simulated NDE.
5. We then do two calculations. In both we use the source NDE function above to throw the events. In one calculation we use the functional form of the original source NDE to correct the neutron yield for the NDE in the analysis. In the second calculation we use the fitted JL function from step 4 in the analysis code to correct the neutron yield for the NDE. We still use the original source NDE function to throw the events.
6. Last, we calculate $R = e_n / e_p$ for each case, take the difference between the two and divide by the average of the two ratio measurements. The result is shown in Figure 2 for the relative uncertainty on GMn. The error bars are statistical ones from the Monte Carlo calculation. The difference in the two parameterizations of the NDE is roughly constant with Q2 and less than 0.5%.

Fig 2. Relative uncertainty in GMn between the two forms of the neutron detection efficiency in the analysis.

```

What worked?

1. Combination of two gaussians with the parameters picked to reproduce the QE W2 spectra ALONE!
2. Make sure you get reduced chisquare about 1.0.
3. Polynomial fit to the IN W2 spectra also ALONE.
4. Combine the two line shapes to fit the summed spectrum.

QE part = 0.986 +/- 0.016
 IN part = 1.39 +/- 0.37

these are consistent with one.

Need better stats to push down the uncertainty.

Now do the neutrons.

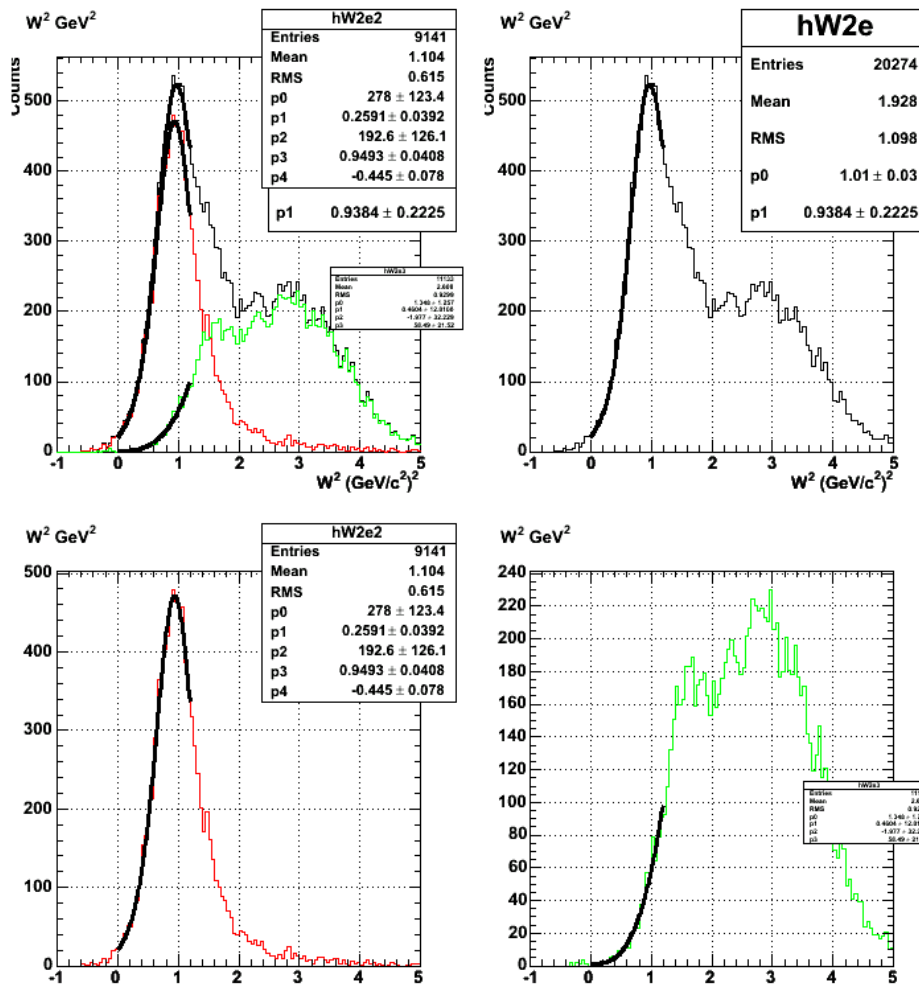

Fig 2. Same as above, but for neutrons. WE actually get better than 1% with these statistics.

Click [here](#) to view the object (ROOT macro) you uploaded.

Extend this a but further. To be more realistic, instead of using the QE and IN W2 spectra that are essentially added to give the summed spectra fitted above, I used the QE and IN spectra I obtained after putting a MM2 cut on the neutron mass (for D(e,e'p)n). At least now I am using lineshapes that are not just given, but actually extracted from the analysis. The results are encouraging as shown below. see log-07-jun-12 for more details. Done with

submit_gmsim.pl 60000 200000 1

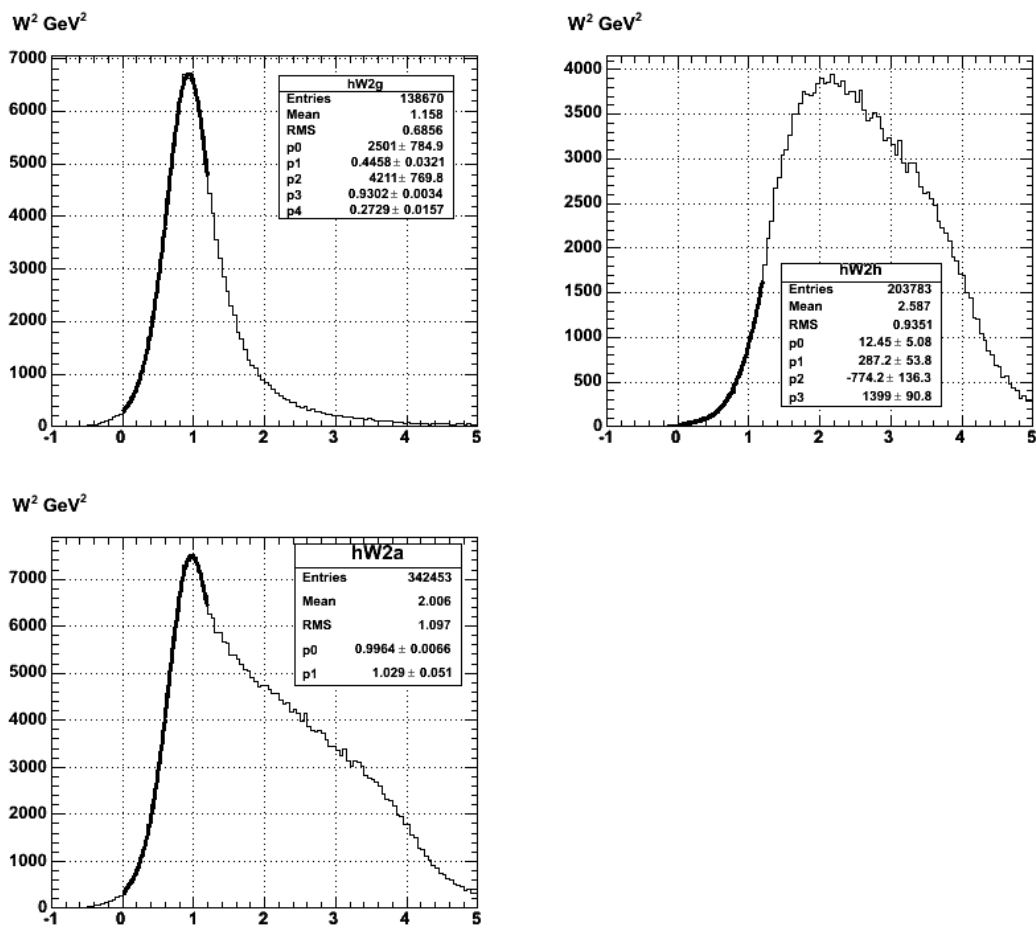

Fig 3. Fitting the W22 spectra to extract the QE events for D(e,e' π)n using lineshapes after applying the MM2 cut to separate QE and IN events.

Jerry Gilfoyle's Enotebook page 181 - theta_pq systematic uncertainty (gpg)

[Modified Tue Jun 12 04:07:37 2007 (GMT) gpg]

Do the test on the systematic uncertainty due to the position of the theta_pq cut the same way as JL. Take the accepted value of the cut, calculate R and then vary the cut by +/- 10% (3.0 deg -> 2.7 deg and 3.3 deg)

Use. submit_gmnsim.pl 30000 100000 1

Files are stored in gmn/theta_pq/run100/

```
fSumw[13]=1.06691, x=6.25, error=0.00642035
fSumw[14]=0.973681, x=6.75, error=0.00672075
```

for theta_pq = 3.3 deg, opps it's still 3 deg.

```
fSumw[13]=1.06691, x=6.25, error=0.00642035
fSumw[14]=0.973681, x=6.75, error=0.00672075
fSumw[15]=0, x=7.25, error=0
```

Jerry Gilfoyle's Enotebook page 182 - Impact of changing theta_pq cut (gpg)

[Modified Sat Jun 16 21:31:24 2007 (GMT) gpg]

To test how changing the theta_pq cut will effect the quasielastic peak and how it will suppress the inelastic background I generated the following figures. Compare fig 1 with fig 1 in entry 178. Done with

submit_gmsim.pl 7000 40000 1

2007-06-15 08:53:36

Fig 1. W2 spectrum with theta_pq < 1.5 deg.

Jerry Gilfoyle's Enotebook page 186 - Getting the inelastic background (gpg)

[Modified Wed Jul 18 02:16:56 2007 (GMT) gpg]

Below are some efforts to fit the inelastic background in hopes of subtracting it out to get the quasielastic production.

2007-07-16 22:50:22

Fig 1. Using a really big polynomial doesn't do a great job.

Click [here](#) to view the object (ROOT macro fir fig 1.) you uploaded.

Click [here](#) to view the object (tar archive of input files for fig 1 from entry 170, second archive.) you uploaded.

Another attempt with the following function.

```
Double_t f10(Double_t *x, Double_t *par)
{
  Double_t arg = 0, fitval, delta;

  arg = x[0];

  // delta = arg - par[0];
  // fitval = par[1]*delta + par[2]*pow(delta,2) + par[3]*pow(delta,3) + par[4]*pow(delta,4) +
  //          par[5]*pow(delta,5) + par[6]*pow(delta,6);

  // change the form to force the function to be zero at W2=0.0 like the simulation.
  // fitval = par[0]*pow(arg,par[1])*exp(-par[2]*(arg-par[3])) + par[4]*pow(arg,par[5]) +
  //          par[6]*exp(-pow(arg - par[7],2)*par[8]);

  fitval = par[0]*pow(arg,par[1])*exp(-par[2]*(arg-par[3])) + par[4]*pow(arg,par[5]);

  return fitval;
}
```

2007-07-17 10:34:53

Jerry Gilfoyle's Enotebook page 187 - Extracting QE sum (Jerry Gilfoyle)

[Modified Tue Jul 24 21:11:36 2007 (GMT) Jerry Gilfoyle]

In preparation for the PAC talk, I am investigating ways to subtract the inelastic background under the QE peak or fit the QE peak. Summary so far:

1. Used a MM2 cut to separate QE and inelastic events. Fitted the low W2 end of the inelastic spectrum to characterize the shape of the background. Fitted the full range of the W2 spectrum for the QE spectrum. Took these two curves and then used a single scale factor multiplying each curve to fit the W2 spectrum for $eD \rightarrow epX$. See entry 180 for more details and log-07-jun-11. This worked for protons at the 1.5% level. I don't know what is the statistical uncertainty for the QE peak.
2. Do a large-statistics run to see if we can reduce the uncertainty. Also, if I try to fit the inelastic spectrum up to higher W2 than in entry 180, I fail to get a good fit. Try just using the spectrum itself as the 'curve'. I screwed up and set the MM2 cut range too large ($MM2 < 1.2 \text{ GeV}^2$) so I have to redo the large-statistics run. Damn!! The plot below shows the MM2 spectrum with an approximate θ_{pq} cut on it (actually used a projection on the MM2-p_m plot and guessed where the QE cut should go).

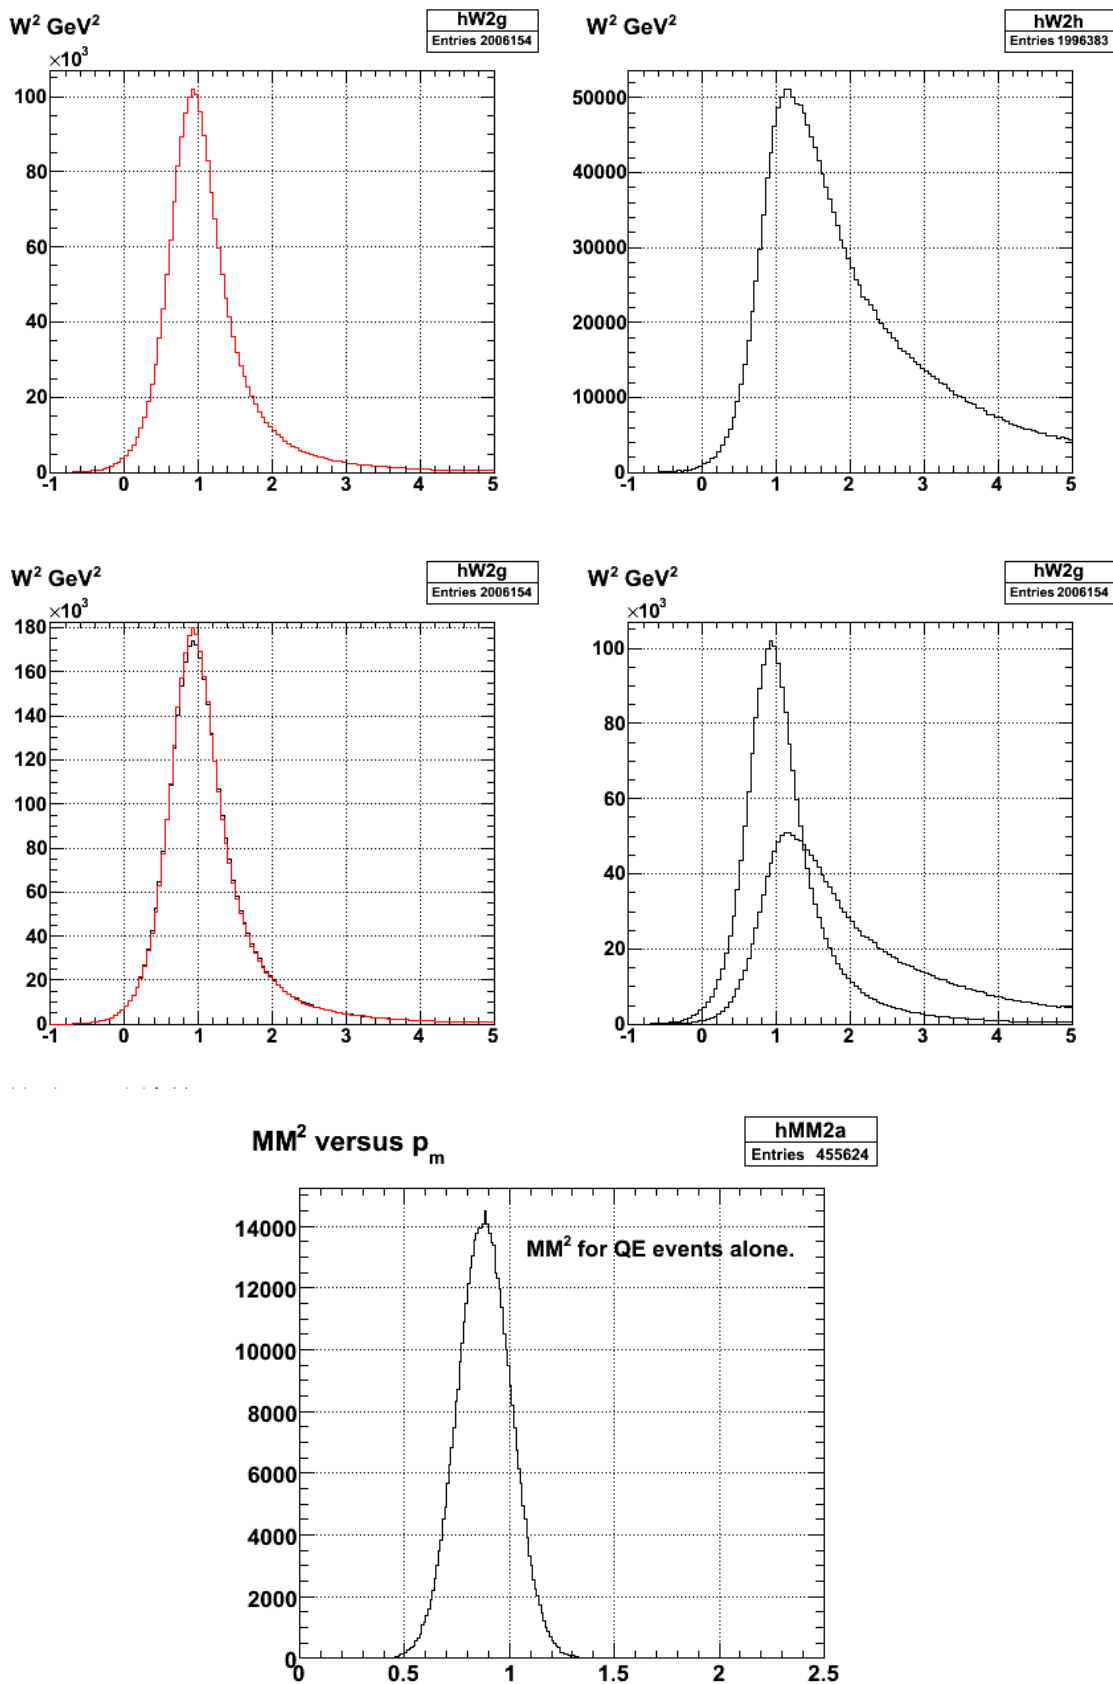

Fig 1. Missing mass squared spectrum.

3. Compare entries 178 and 182 and 183 to see the effect of shrinking θ_{pq} to reduce the background in the W2 spectrum under the QE neutrons.

2007-07-21 15:50:01

Fig 3. Shows the problem with the MM2 cut. The MM2 distribution is very wide so the cut I'm using throws out lots of events especially at high W2

so the W^2 distribution with the cut is significantly different from the one in the uncut W^2 distribution.

2007-07-21 17:41:17

Fig 4. Realistic statistics for $Q^2 = 6-7 \text{ GeV}^2$, θ_{pq} cut = 3 deg.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (gzipped tar file of histograms.) you uploaded.

2007-07-24 16:25:30

Fig 5. Fit of the individual, high-stats QE and IN W^2 spectra to a low-stats run.

Click [here](#) to view the object (ROOT macro) you uploaded.

Jerry Gilfoyle's Enotebook page 188 - PAC talk (gpg)

[Modified Fri Jul 27 18:50:41 2007 (GMT) gpg]

PAC talk (7/27/07 14:50).

Click [here](#) to view the object (reduced version) you uploaded.

Click [here](#) to view the object (talk1) you uploaded.

Jerry Gilfoyle's Enotebook page 189 - Q2=12-14 GeV2 (gpg)

[Modified Fri Aug 3 18:18:01 2007 (GMT) gpg]

To see the limits I am looking at the separation of the QE from the background at the last Q2 bin. Done with the following command.

```
submit_gmsim.pl 7000 40000 1
```

2007-07-29 22:07:52

Fig 1. W2 comparison for QE (red), inelastic (blue) and total (black) for Q2=12-14 GeV2 from PART banks.

Click [here](#) to view the object (ROOT macro for figs 1-2) you uploaded.

Click [here](#) to view the object (tar archive with inputs for fig 1) you uploaded.

2007-07-29 22:22:28

Fig 2. Same as fig 1 for evt bank.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now reduce the theta_pq limit from 3 deg to 1.5 deg.

2007-07-29 23:24:07

Fig 3. Same as fig 2 for $\theta_{pq} < 1.5 \text{ deg.}$

2007-10-03 22:26:27

Fig 7. Difference between TOF calculated using beta from tracking and beta for the neutron calculated using the 3-momentum transfer q from the

electron kinematics. Used the path length ec_r for the EC in both cases, θ_{pq} cut, and restricted $1.7 \text{ GeV}/c < p_n < 2.7 \text{ GeV}/c$.

Click [here](#) to view the object (ROOT macro) you uploaded.

I had turned off a bunch of cuts for use with FASTMC and I forgot to turn them back on for the gmn data analysis. The revised results are in the next figure. The biggest effect now is there are fewer counts.

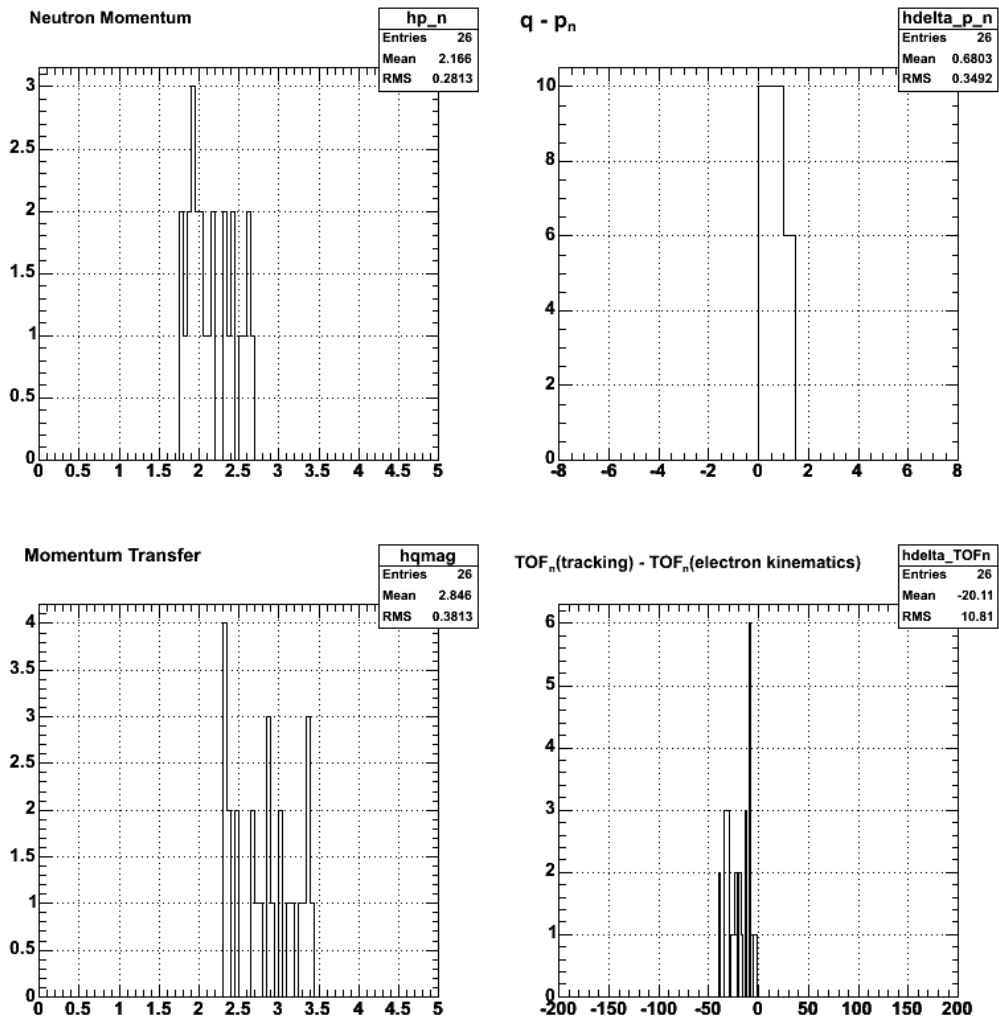

Fig. 8 Same as Fig 7 with all the normal cuts on.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now turn off the electron fiducial cuts.

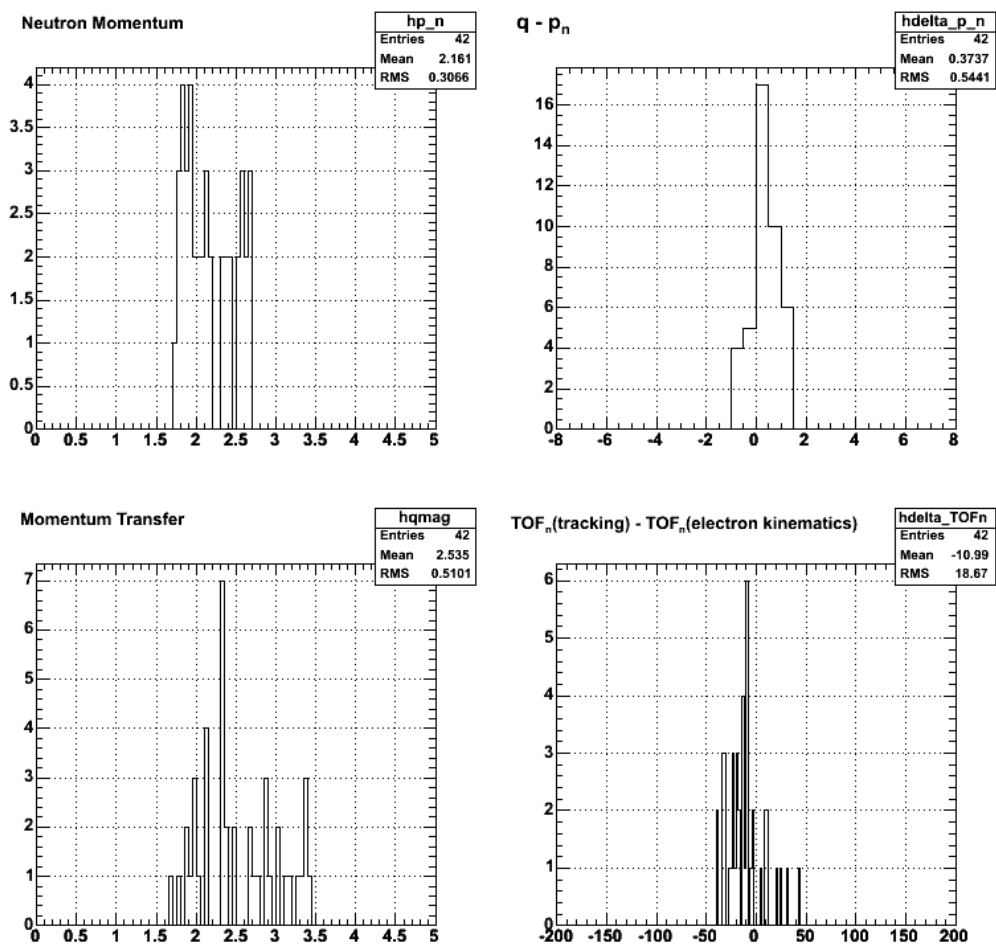

Fig. 9 Same as Fig 8 with the electron fiducial cuts turned off.

Click [here](#) to view the object (ROOT macro) you uploaded.

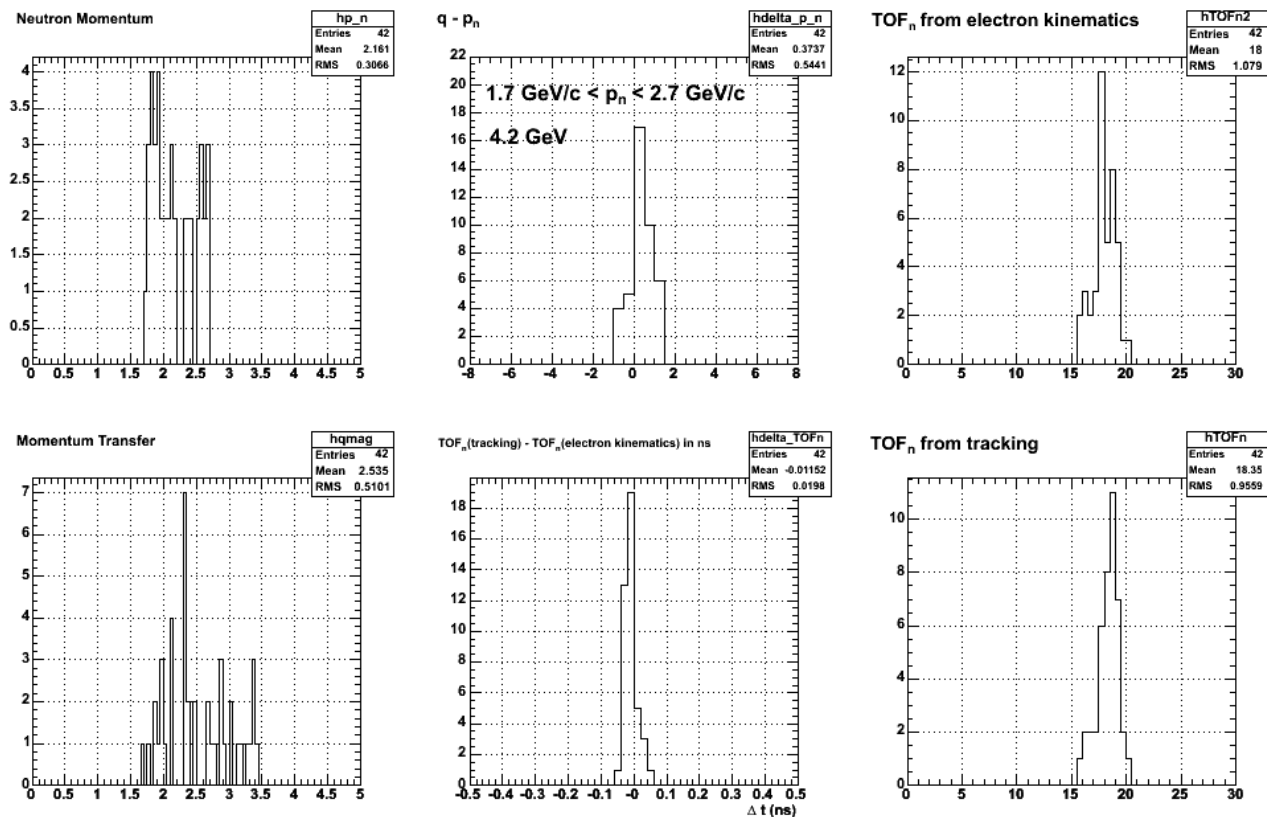

Fig 10. Same as fig 9 with TOF spectra added.

Click [here](#) to view the object (ROOT macro) you uploaded.

OK! Fix the stupid mistakes and the delta_TOF spectrum now looks more reasonable with a width comparable to the width in the delta_toF figure in the CAN.

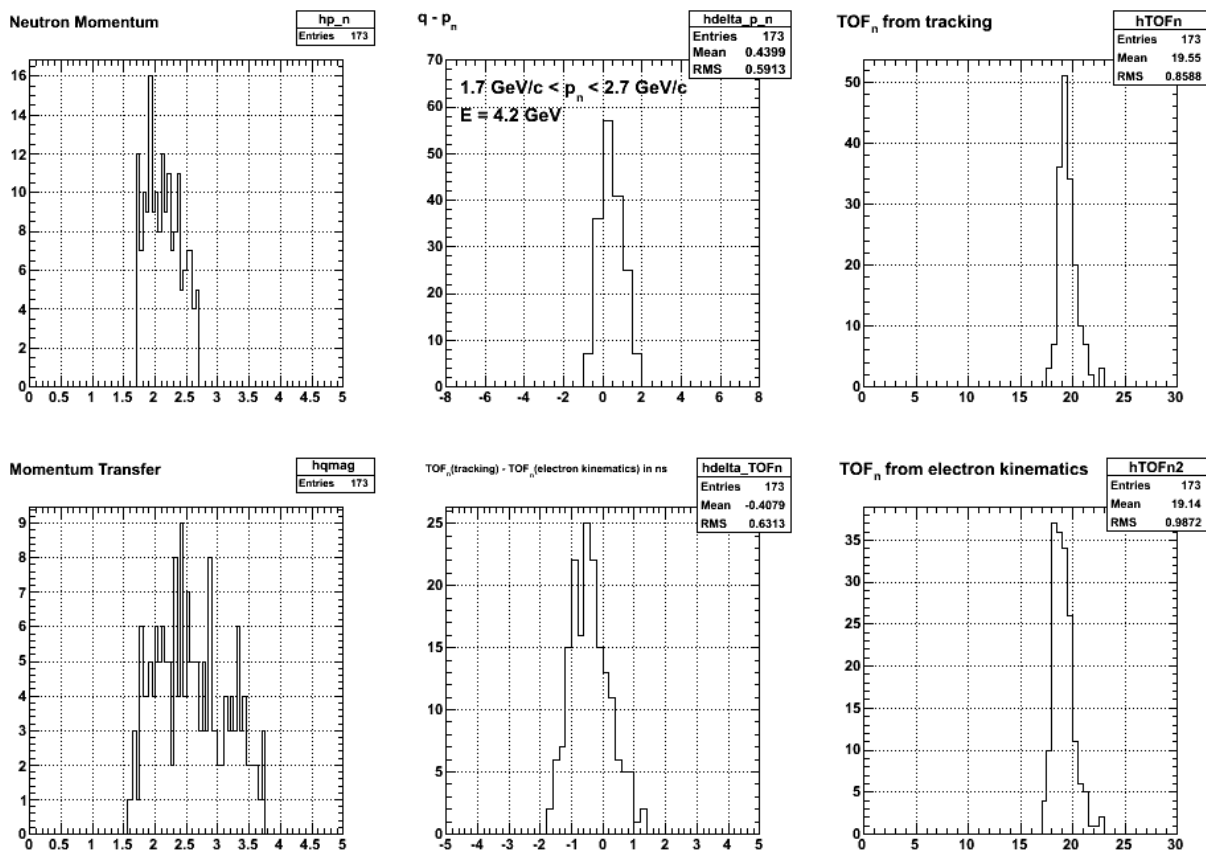

Fig 11. Same as 10 with corrections to scale for delta TOF spectrum.

Reccis

The CLAS reconstruction and analysis package (RECSIS) has been modified to read data from the CLAS event transfer (ET) system so users can do other complex analyses during data acquisition on a down-scaled subset of the incoming data. The capability of reading the ET system is part of performing offline analyses can quickly and easily generate a version of their code that can be used during data collection.

Send questions, complaints, flames, and such to gilfoyle@jlab.org.

Building RECSIS

For example to build release-4-17 do following on *clon04* machine:

```
cd /usr/local/clas/offline/clas/builds
mkdir release-4-17
cd release-4-17
setenv CVSROOT /u/group/clas/clas_cvs
cvs co online_source
cd packages
gmake lib ONLINE=YES
gmake exe ONLINE=YES
```

Running RECSIS

First, point PRODUCTION to the desired release, for example:

To start RECSIS_ONLINE use following commands (for our example):

```
setenv CLAS_ROOT /usr/local/clas/offline/clas
cd $CLAS_ROOT/build
rm PRODUCTION
ln -s release-4-17 PRODUCTION
```

```
source $CLAS_ROOT/builds/PRODUCTION/packages/cms/clon.cshrc PRODUCTION
setenv LD_LIBRARY_PATH /usr/lib/mysql:$LD_LIBRARY_PATH
#setenv LD_LIBRARY_PATH $CODA/sunos_sun4u/lib:$LD_LIBRARY_PATH
setenv RECSIS_RUNTIME $CLON_PARMS/recon/
chdir /usr/clas/archives/hist/recon
setenv LD_LIBRARY_PATH .:${LD_LIBRARY_PATH}
$CLAS_ROOT/builds/PRODUCTION/bin/LinuxRHEL4/recon -a clasprod $CLON_PARMS/recon/recon.tcl
```

Jerry Gilfoyle's Enotebook page 198 - First look at low-Q² R problem (gpg)

[Modified Fri Jan 18 19:58:05 2008 (GMT) gpg]

The plots below show a very preliminary look at the low-Q² GMn R. They reproduce qualitatively the problem Jeff saw at the lowest Q² (see fig 1 and entry 375 in E5 elog) where it appears that we are losing proton events. However, the quantitative agreement is not great (see Fig 2). It almost appears as if my spectra are shifted one bin (about 0.15 GeV²) higher than Jeff's.

Fig 1. Plot from entry 375 in E5 elog from JL showing problem at low Q² for 2.6r data.

 Fig 2. Preliminary look at R at low Q2. No efficiency or Fermi corrections; just raw spectra divided to get R.

Click [here](#) to view the object (ROOT macro for fig 2.) you uploaded.

θ_e VS ϕ_e

hphie_thetae

2008-01-18 11:50:56

Fig 3. The canyon.

Click [here](#) to view the object (ROOT macro for fig 3) you uploaded.

Turn off the electron fiducial cuts just for the e-p events and you get the following. Many more e-p events get in at lower Q2 and there is not a dip in this region any more.

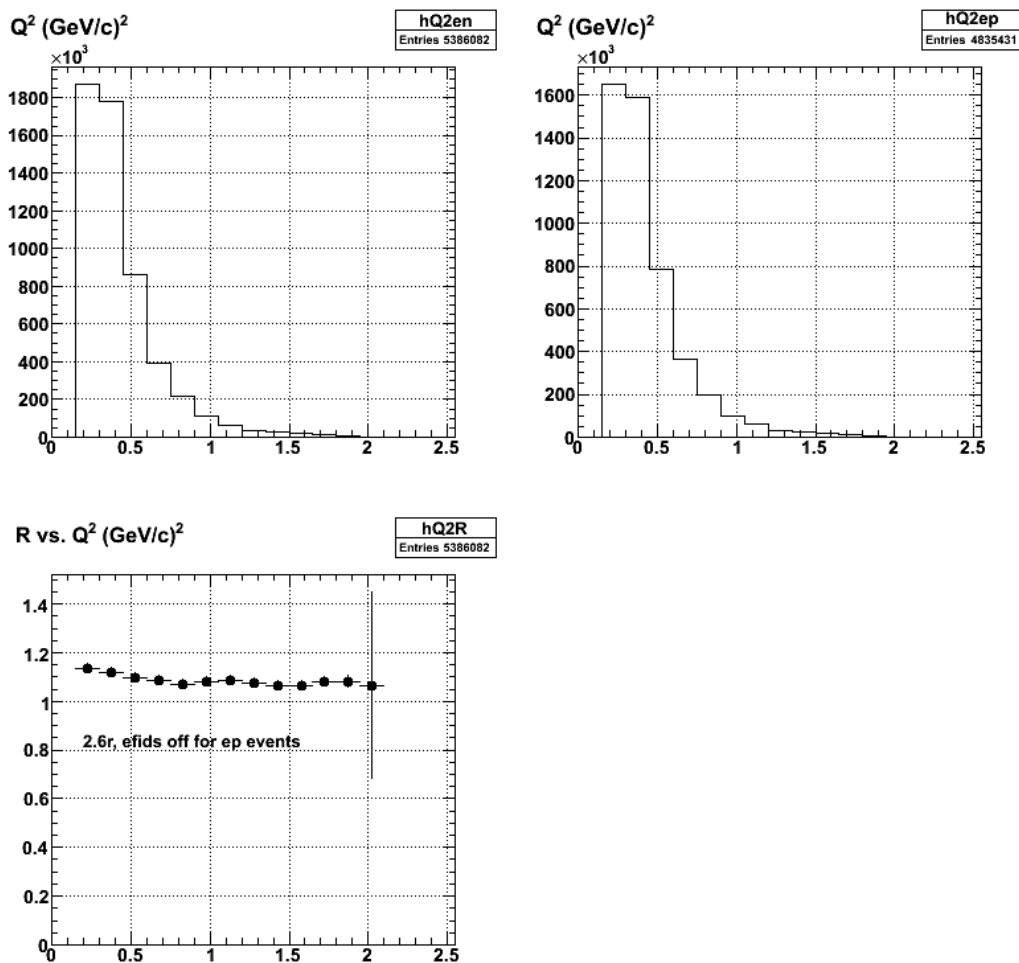

Fig 4. Effect of turning off electron fiducial cut only on e-p (and not e-n) events.

Click [here](#) to view the object (ROOT macro for fig 4) you uploaded.

EEEEEEKKKKK! None of the analysis done above had the electron fiducial cuts turned on for the e-n events so Fig 4 is the best comparison. It does not show the sharp rise at low Q^2 , but does not extend down as far as JL's spectra.

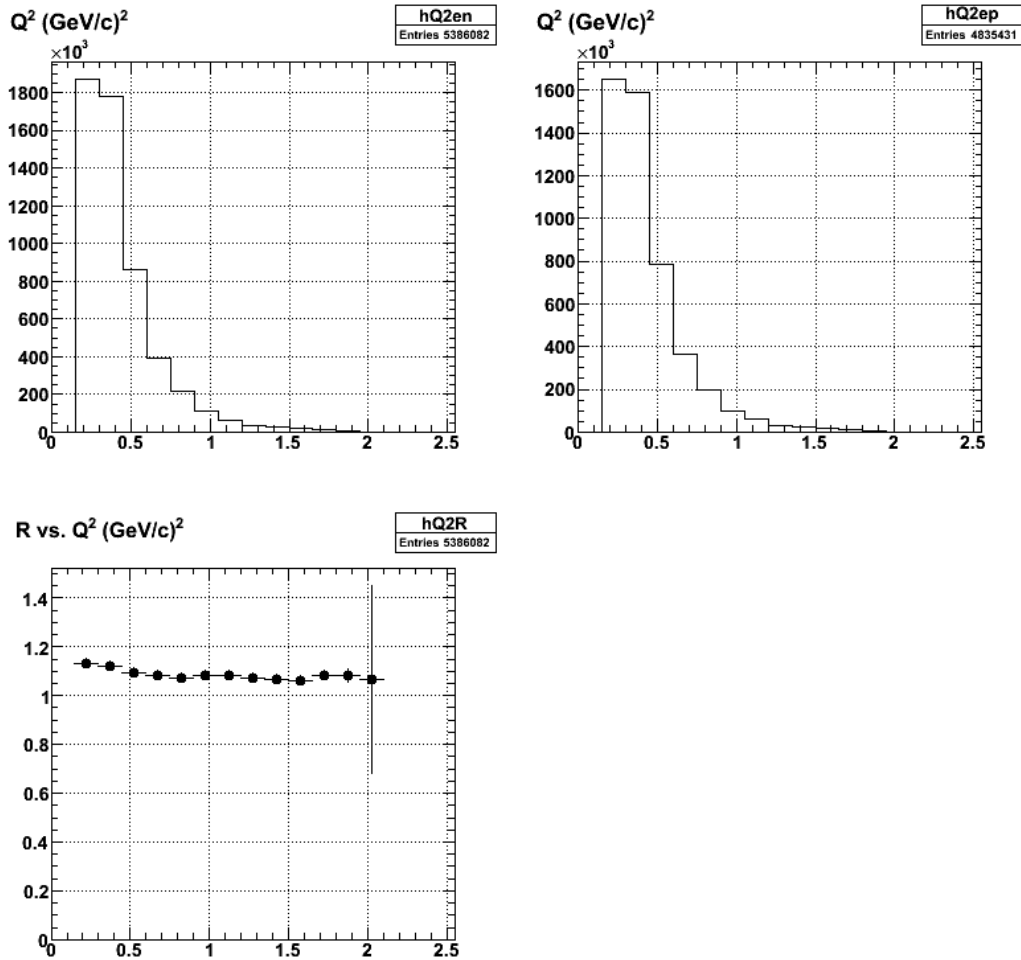

Fig 5. Effect of canyon cut - virtually no effect.

Click [here](#) to view the object (ROOT macro for fig 5) you uploaded.

Jerry Gilfoyle's Enotebook page 199 - KD sim12 plots (gpg)

[Modified Wed Jan 30 19:26:33 2008 (GMT) gpg]

First plots from Kirill for his senior seminar.

Jerry Gilfoyle's Enotebook page 200 - EOD checks including proton mass wings (gpg)

[Modified Tue Mar 15 02:04:22 2011 (GMT) gpg]

Huh!!!??

2008-02-02 10:08:09

Fig 1. MM2 vs p_m

I did not reset the jneutron index in the code which created an indexing problem and misalignment of the momenta.

2008-02-03 17:50:45

Fig 2. MM2 vs. missing momentum p_m for 2.6r with the usual cuts OFF.

Click [here](#) to view the object (ROOT histogram file for fig 2) you uploaded.

2008-02-03 18:03:38

Fig 3. p_p vs. m_p plot showing the famous mass 'wing' due to (i think) events where the wrong beam bucket was chosen for the final timing calculation.

Turn on all the normal cuts include efids and pfids.

2008-02-03 20:08:29

Fig 4. MM^2 vs. missing momentum p_m for 2.6r with the usual cuts turned ON.

Click [here](#) to view the object (ROOT histogram file for fig 4.) you uploaded.

Turn on the proton mass cut 0.88-1.02 GeV/c².

2008-02-03 21:16:38

Fig 5. MM2 vs. missing momentum p_m for 2.6r with the usual cuts turned ON and the proton mass range of 0.88-1.02 GeV/c².

Put a narrow cut on the proton mass 0.92-0.97 GeV/c².

2008-02-03 22:31:01

Fig 6. MM2 vs. missing momentum p_m for 2.6r with the usual cuts turned ON and the proton mass range of 0.92-0.97 GeV/c².

Click [here](#) to view the object (ROOT histogram file for fig 6.) you uploaded.

Now do the 2.6n data set with all the same cuts as the previous analysis for fig 6.

2008-02-04 09:45:15

Fig 7. MM2 vs. missing momentum p_m for 2.6n with the usual cuts turned ON and the proton mass range of 0.92-0.97 GeV/c2.

Click [here](#) to view the object (Root histogram file for fig 7.) you uploaded.

Now do 4.2 with all the same cuts as fig 7.

2008-02-05 16:01:25

Fig 8. MM2 vs. missing momentum p_m for 4.2n with the usual cuts turned ON and the proton mass range of 0.92-0.97 GeV/c2.

Click [here](#) to view the object (Root histogram file for fig 8.) you uploaded.

Jerry Gilfoyle's Enotebook page 201 - GMn Neutrons (gpg)

[Modified Fri Feb 29 21:45:00 2008 (GMT) gpg]

Below is my first look at the neutron spectra as part of extracting GMn from the lowest Q2. The EC goes out to 45 deg and the break between the EC and LAC is clear in the right-hand panel. There is no cuts on these spectra like $\theta_{pq} < 3$ deg to isolate QE events.

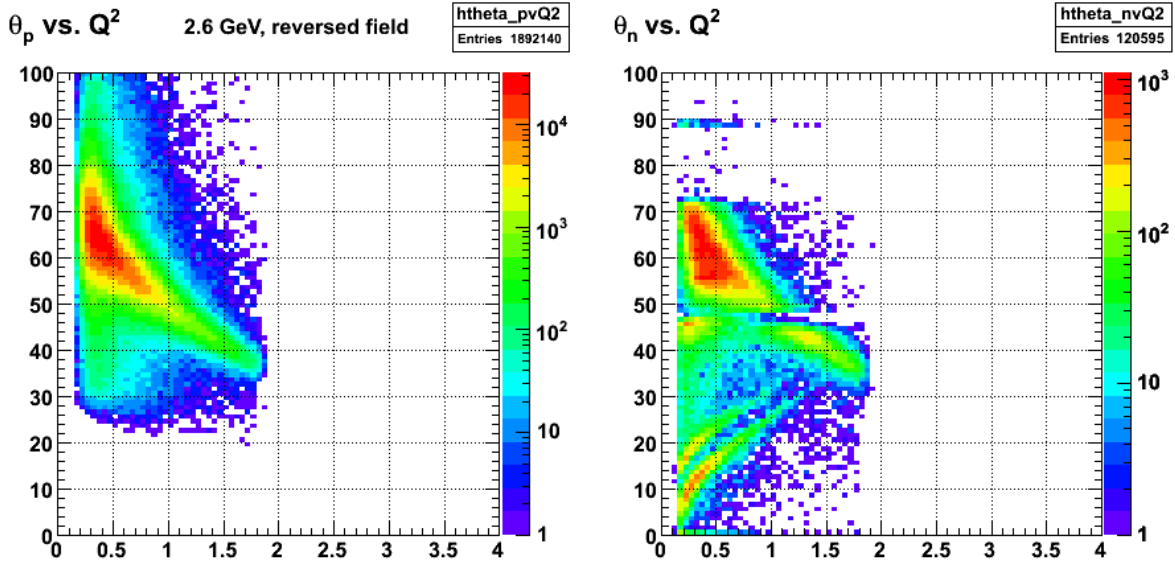

Fig 1. Nucleon angle versus Q2 for 2.6r.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Project out the angular distribution for each nucleon.

Fig 2. Angular distribution of nucleons. No QE cut.

Theta_pq for neutrons and protons. First, cuts on protons.

```
if (ep_event &&
    target_walls_ep &&
    quasielastic_cut &&
    //dip_cut &&
    //delta_cut &&
```

```

Still have the threshold problem at Q2 = 0.5 GeV2!!!

2008-04-16 15:06:46

Fig 12. Neutron distribution for all sectors with EC efficiency cut off.

Click [here](#) to view the object (ROOT macro for Fig 12) you uploaded.

Modify the cuts so that everything with $Q2 < 0.5$ GeV² gets in.

```
if(qe_in.type == qe_NEUTRON){
  if(use_ec == true_){
    //cout << "found an EC neutron! check_cuts and check_fiducial=" << check_cuts(qe_in,EC) << " " << check_fiducial(qe_in,EC) << " !" << endl;
    if (qe_in.qsq < 0.5) cout << "Q2=" << qe_in.qsq << " check_cuts and check_fiducial=" << check_cuts(qe_in,EC) << " "
      << check_fiducial(qe_in,EC) << " !" << endl;
    if((check_cuts(qe_in,EC)==true_ && check_fiducial(qe_in,EC)==true_) || (qe_in.qsq < 0.5)){
      ec_hit = ec_geom->calc_xyz(vert,nucleon3);
      ec_pix = ec_geom->xyz2pixel(ec_hit);
    }
  }
}
```

Now see lots of events.

2008-04-16 21:31:44

Fig 13. Effect of letting all $Q2 < 0.5$ GeV² events in.

Click [here](#) to view the object (ROOT macro for fig 13) you uploaded.

In examining the log files it is clear that the code is picking the wrong polarity for the torus current. after adding the following stuff to my .cshrc file things get better.

```
# for GMn analysis
```

```
setenv CLAS_CALDB_RUNINDEX calib_user.RunIndexe5
setenv RUN_INDEX calib_user.RunIndexe5
```

In particular, the torus current is now usually correct in the outputs from the SDA and other CLAS routines. There are a number of places where it is still positive when it should be negative. In printing out the torus current from the functions in JL's code, it is now clear there are still problems. The C++ structure `qe_in` which it looks like JL's code gets from the ntuple created in the event selection phase has a member `qe_in.Itorus` which is still positive. I arbitrarily set this value to negative in JL's code to see the effect and I now see events below $Q2 = 0.5$ GeV². See plots below.

Jerry Gilfoyle's Enotebook page 204 - GMn R2 (gpg)

[Modified Tue Apr 29 00:17:18 2008 (GMT) gpg]

Now that the code appears to be working take a look at the behavior of neutrons and protons as functions of momentum and theta to try and figure out the low-Q2 problems in the e-n/e-p ratio that JL sees (see entries 375 and 381 in E5 log). Fig 1 shows the momentum and angle dependence for neutrons and protons with the fiducial cuts (check_fiducial) and the quasielastic cut on theta_pq (check_cuts).

All of the analysis below is based on runs 24519-24520. Some plots are fulls analysis of both of these and some are partial analysis of these runs.

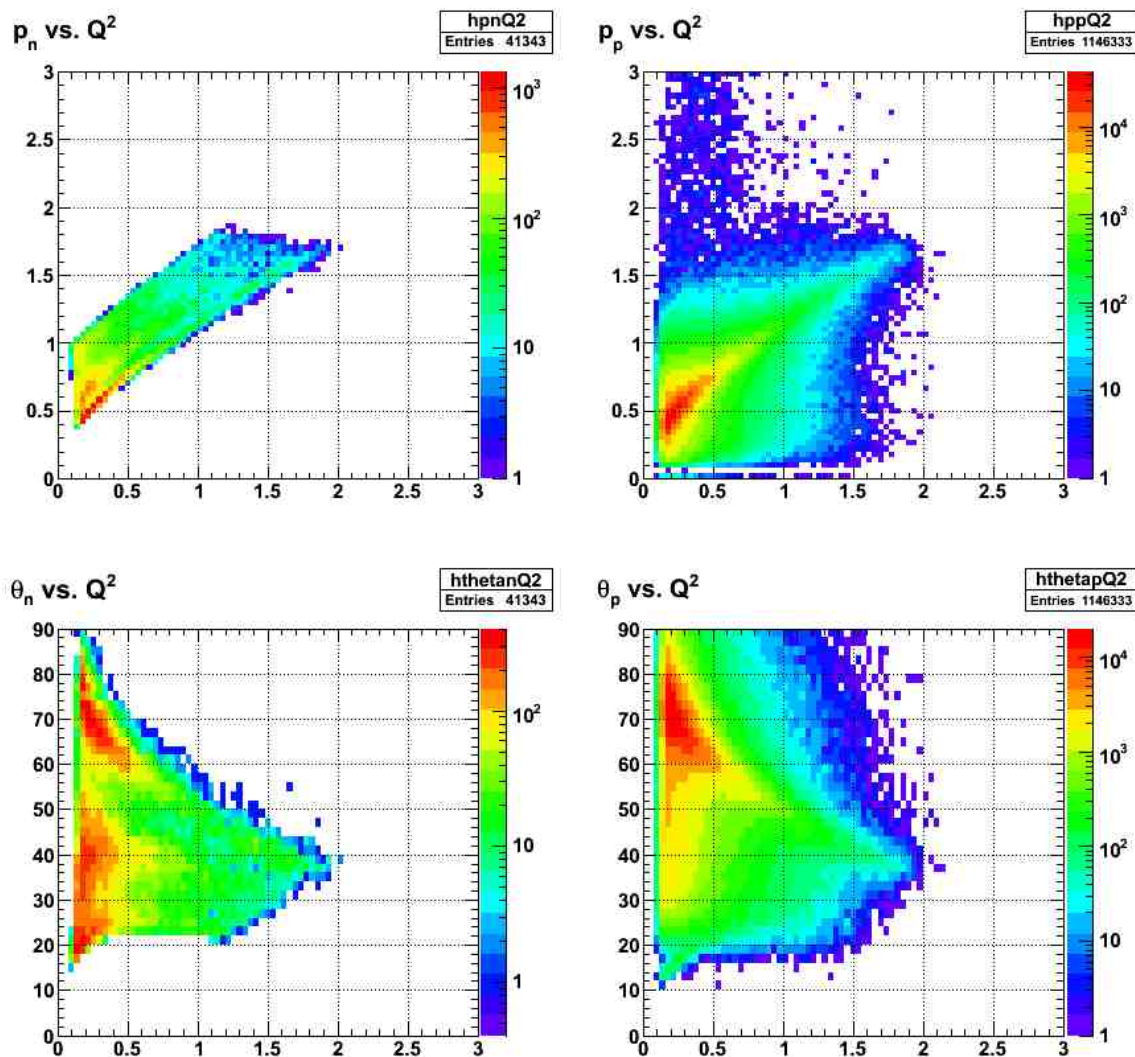

Fig 1. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (ROOT histogram file for fig 1) you uploaded.

Now turn on check_cuts and check_fiducial and get Fig 2. What is that nasty thing for Q² < 0.5 GeV²?

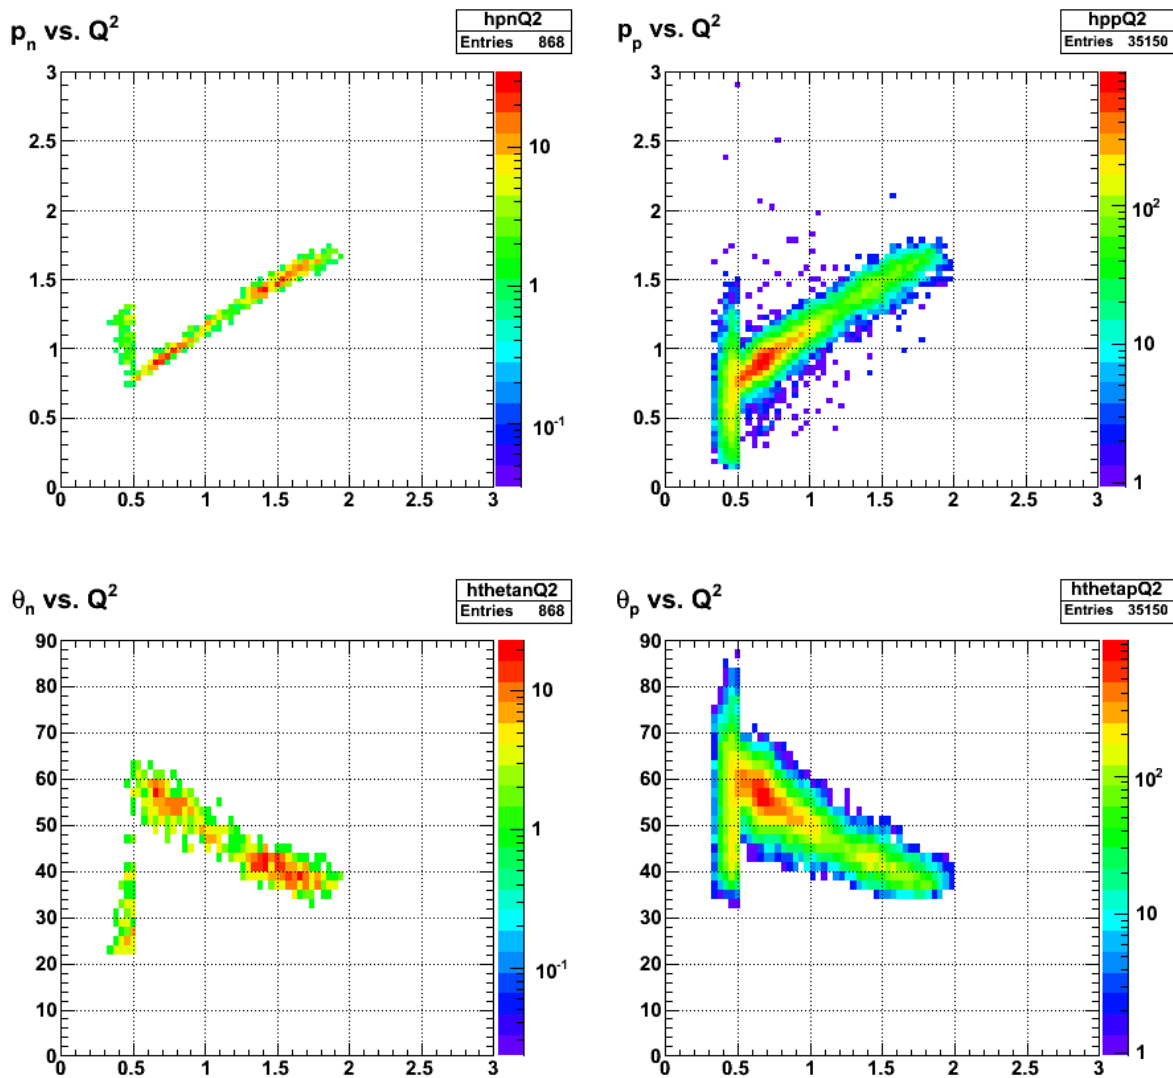

Fig 2. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana. The results are for all detectors (ec, lac, sc) and with check_cuts and check_fiducials turned on.

Click [here](#) to view the object (ROOT macro for fig 2) you uploaded.

Now turn off the SC in the analysis that fills the hists.

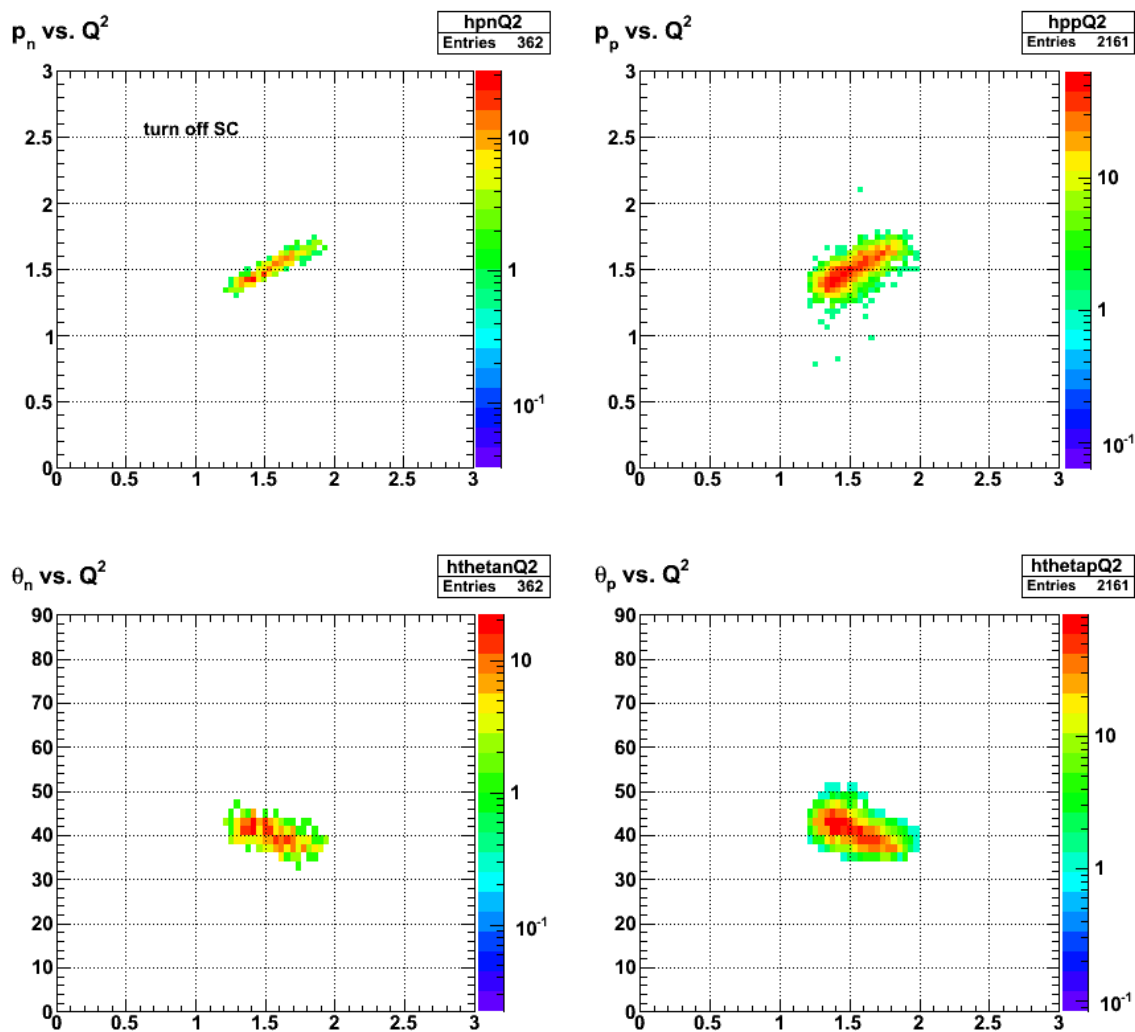

Fig 3. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana. The results are for all detectors (ec and lac; sc is off) and with check_cuts and check_fiducials turned on.

Click [here](#) to view the object (ROOT macro for Fig 3) you uploaded.

Turning off the LAC has no effect on the results in Fig 3. I was suspicious that the weirdness below $Q^2 = 0.5$ GeV² was due to the efficiency so I set the weight to 1.0 for all events with little change.

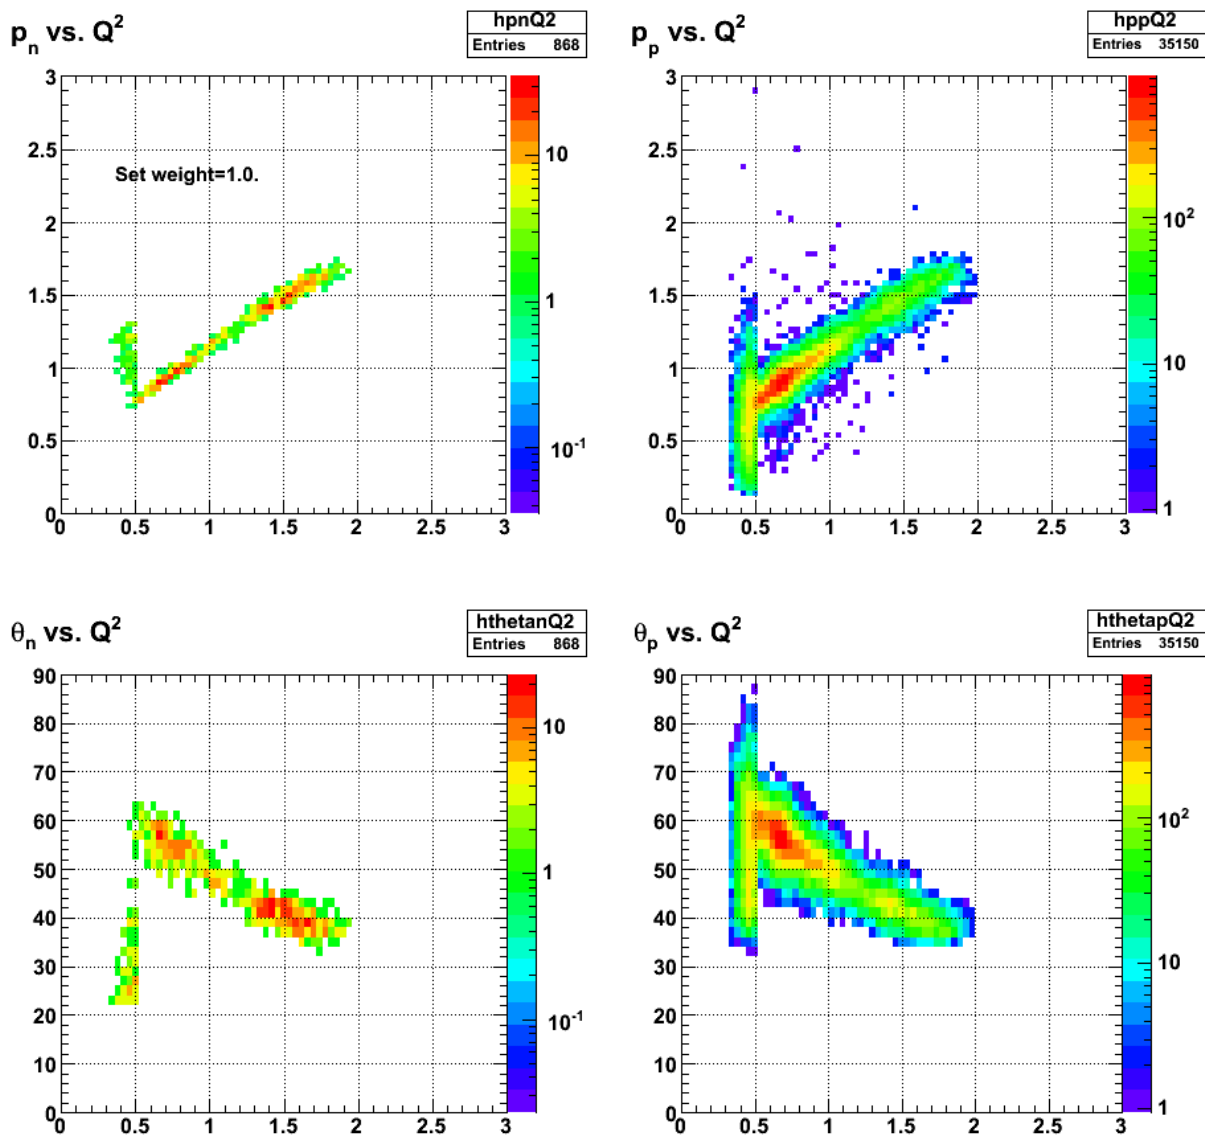

Fig 4. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana. The results are for all detectors (ec and lac; sc is off) and with check_cuts and check_fiducials turned on and weight = 1.0

Click [here](#) to view the object (ROOT macro for fig 4) you uploaded.

Set the weight=1/nde in the 2D histograms and see if there is any significant difference. There is not.

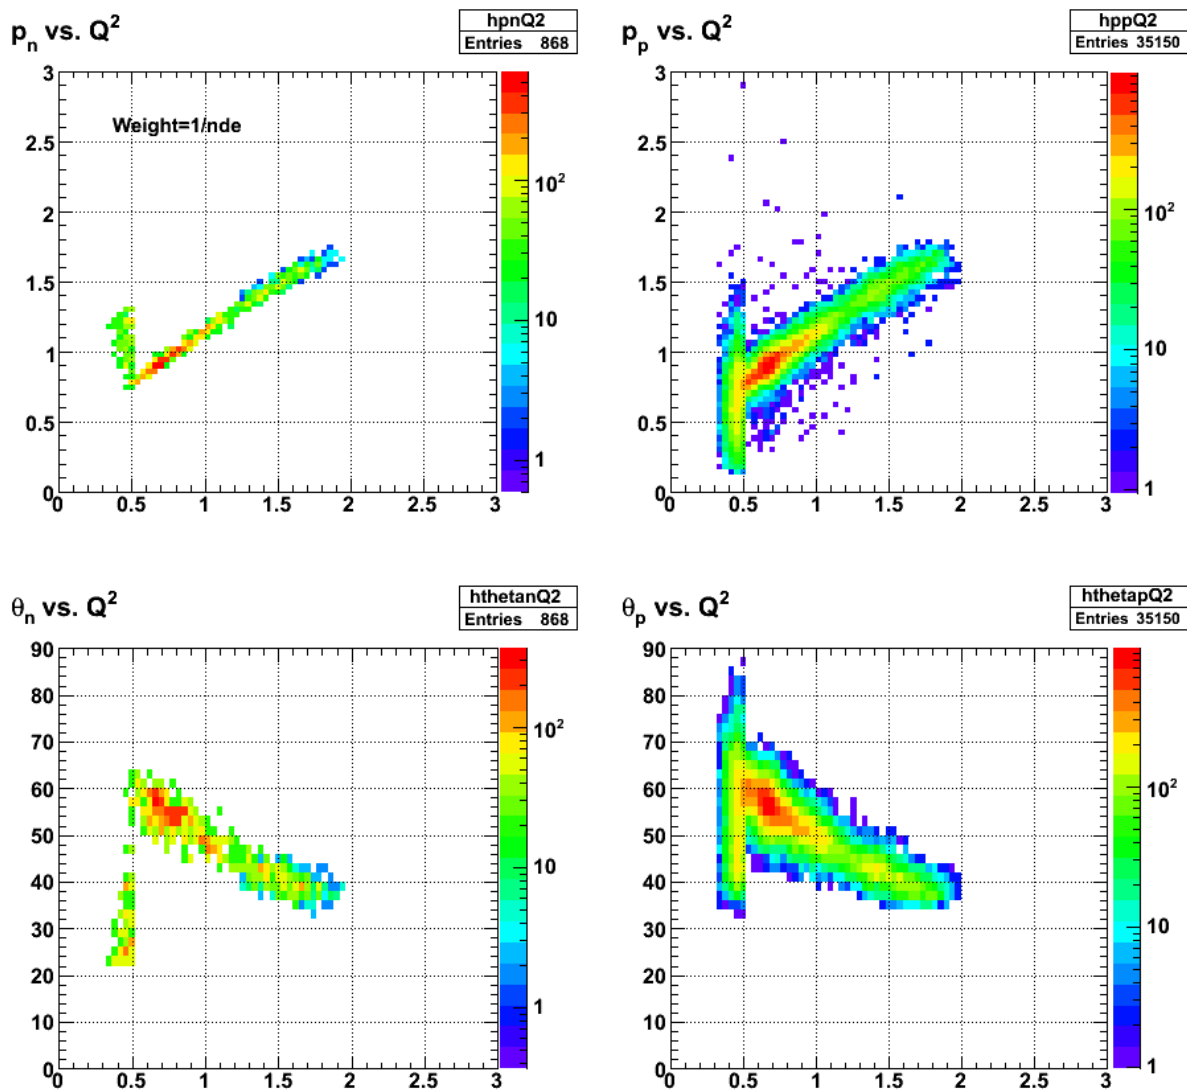

Fig 5. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana. The results are for all detectors (ec and lac; sc is off) and with check_cuts and check_fiducials turned on and weight = 1/nde.

Click [here](#) to view the object (ROOT macro for fig 5) you uploaded.

The problem is clearly in the SC so start looking at the SC alone.

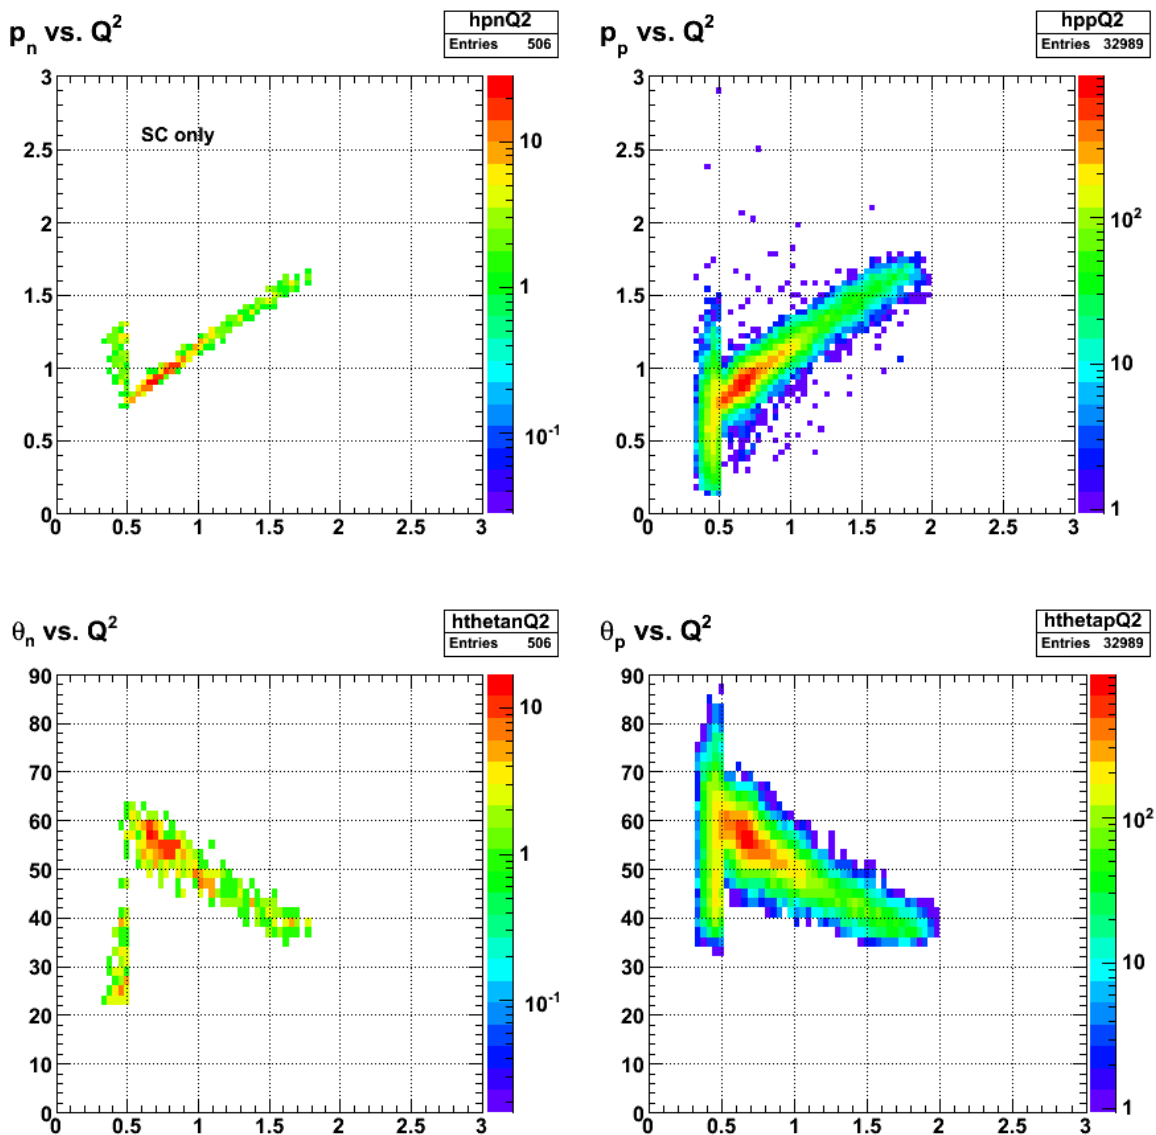

Fig 6. Momentum and angle dependence for neutrons (left) and protons (right) for 2.6r from qe_ana. The results are for all detectors (ec and lac; sc is off) and with check_cuts and check_fiducials turned on and weight = 1.0, SC only.

Entries 12

2008-05-05 23:38:03

Fig 8. Effect of including cuts for $Q^2 < 0.5 \text{ GeV}^2$ on reduced GMn (red) for 2.6r data. Black points are from previous analysis where cuts were turned off for $Q^2 < 0.5 \text{ GeV}^2$.

Click [here](#) to view the object (ROOT macro for fig 8) you uploaded.

Click [here](#) to view the object (ROOT histogram file for fig 8.) you uploaded.

'Fix' the problem with turning off the cuts for $Q^2 < 0.5 \text{ GeV}^2$ and start looking at things. We want to optimize the cuts for this region. The 595-event plots are from events that are outside cut1. The 646-event plots are for all events.

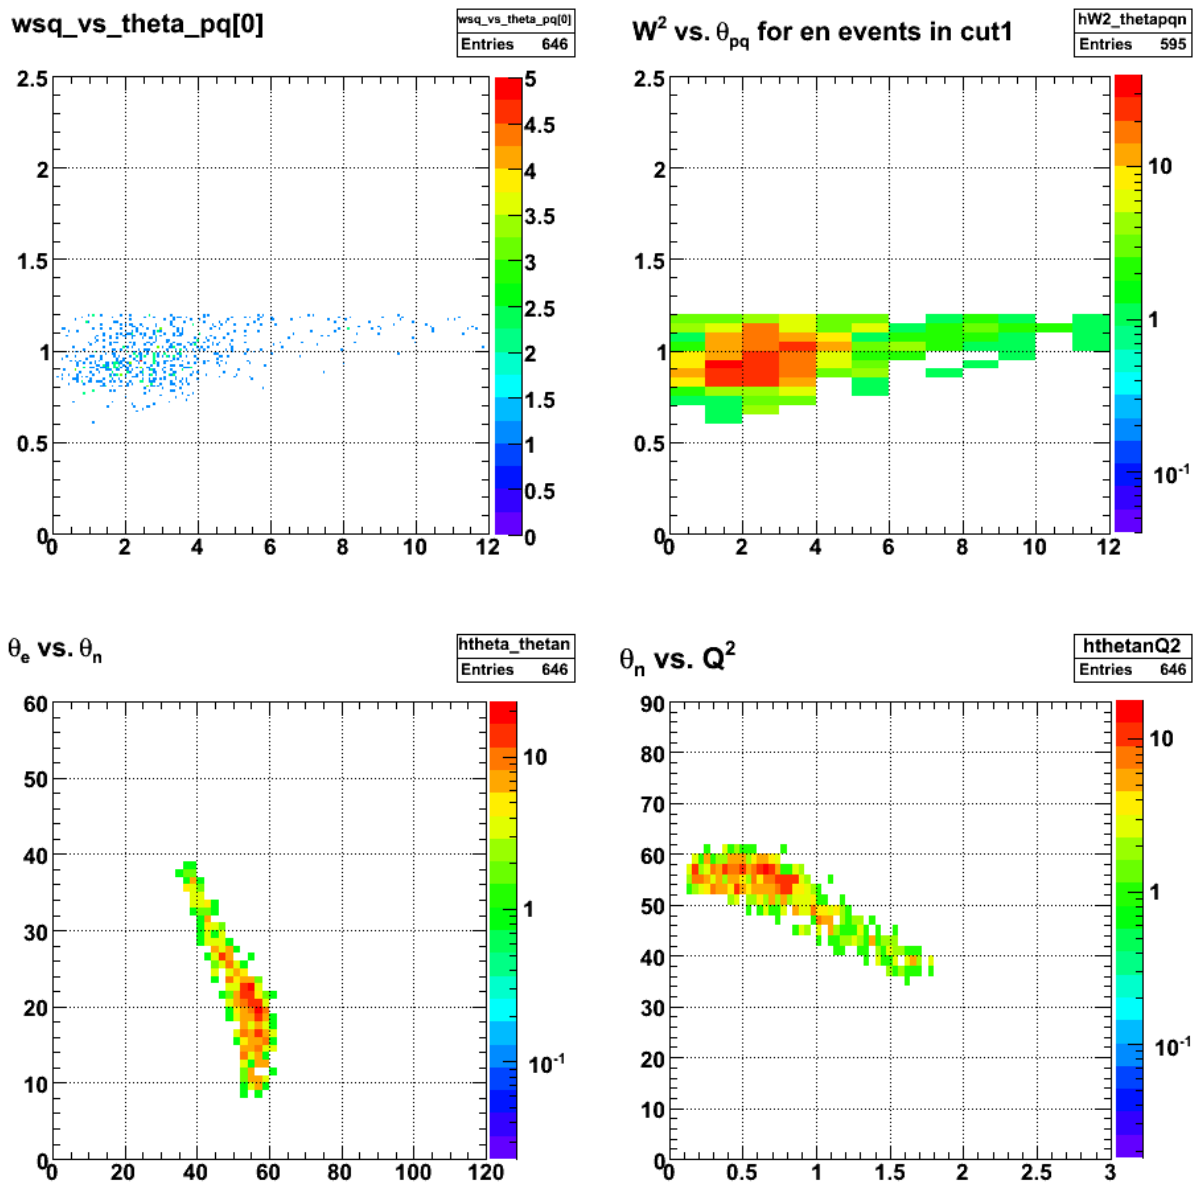

Fig 9. Neutrons a 2.6r.

Click [here](#) to view the object (ROOT macro for fig 9) you uploaded.

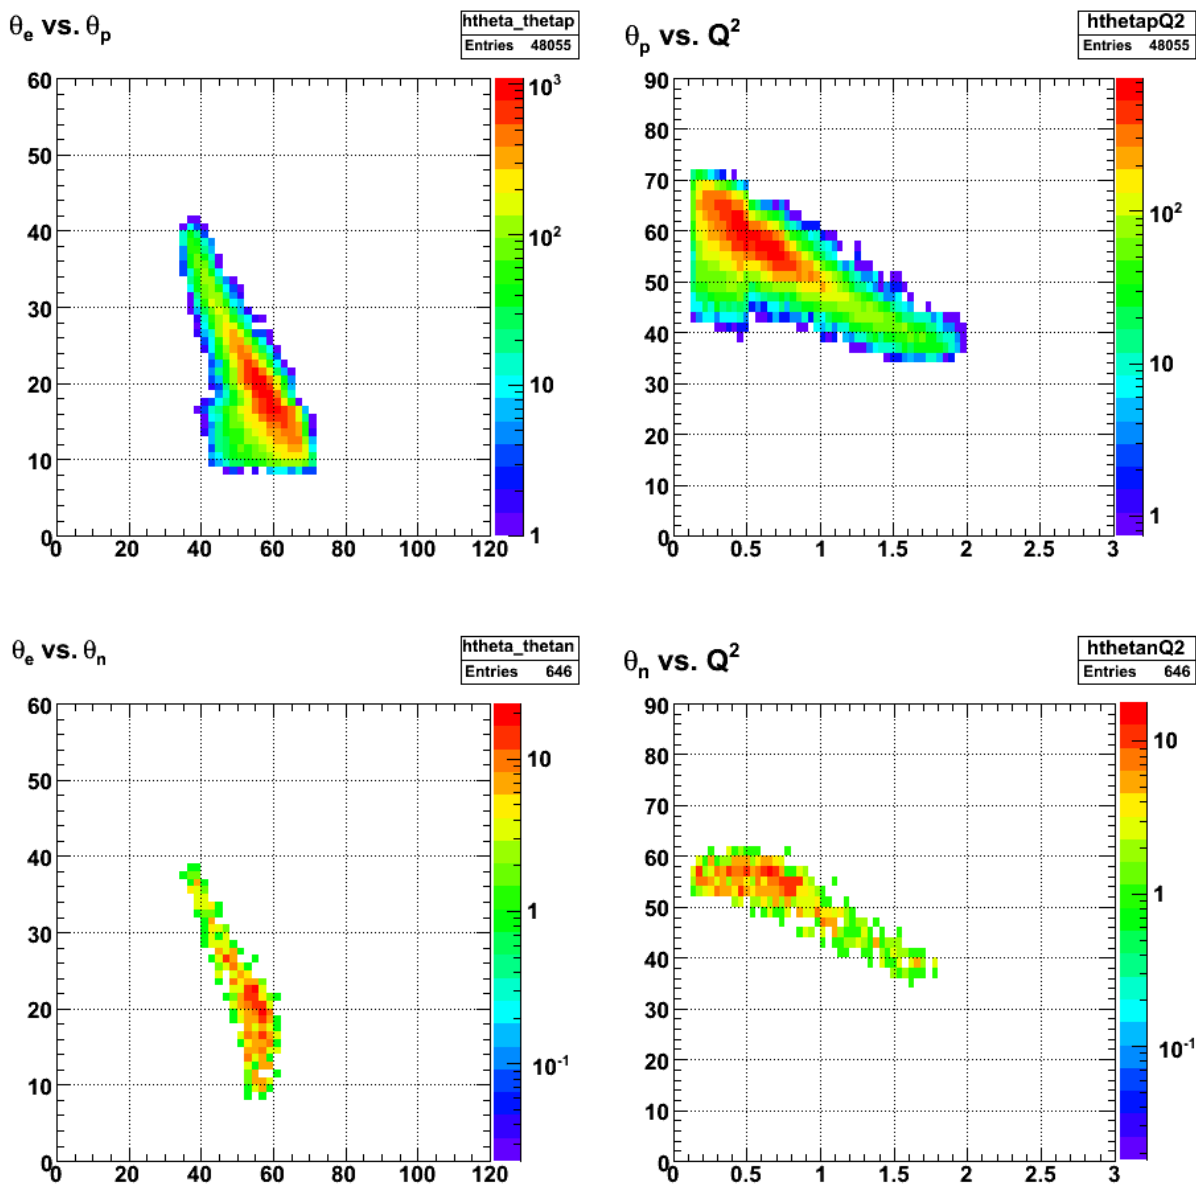

Fig 10. Compare neutrons (bottom row) with protons (top row). Why is there such a disparity in the number of neutrons versus protons???

Click [here](#) to view the object (ROOT macro for fig 10) you uploaded.

The difference in the number of events is real. The difference in the distribution of neutrons versus protons (i.e. fig ?) is much less because the efficiency is smaller for the neutrons in the SC so each event counts more. The plot below shows the θ_e versus θ_N weighted by $1/\text{det eff}$.

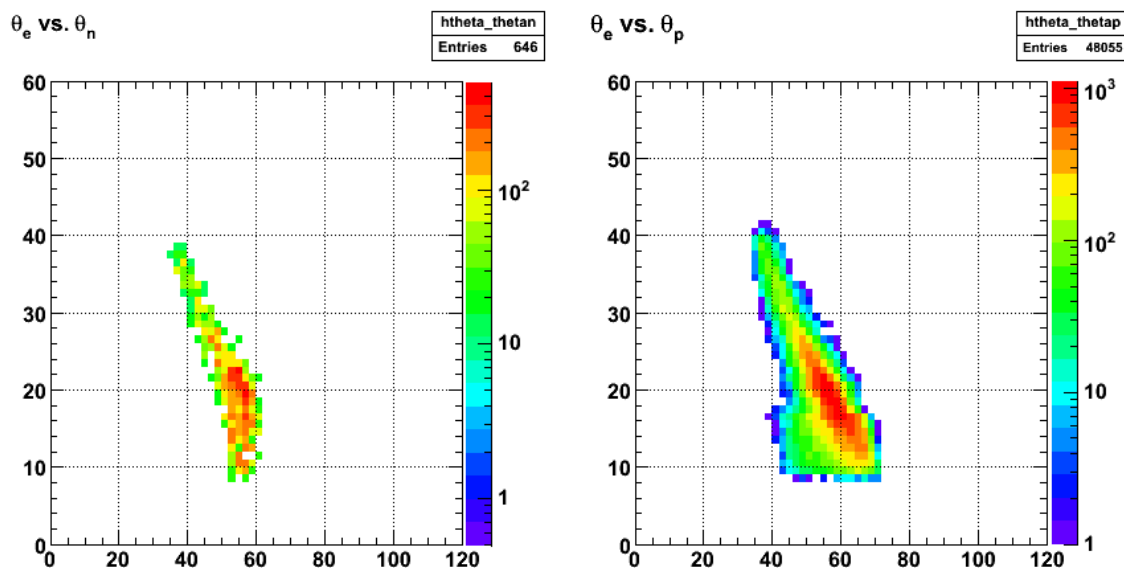

Fig 11. Electron angle versus nucleon angle for neutrons (left) and protons (right).

Click [here](#) to view the object (ROOT macro for fig 11.) you uploaded.

The distributions in Fig 11. have two major problems. They should look roughly the same since the acceptance matching is turned on. Thus, the apparent cutoff in the neutrons at $\theta_n = 60$ deg is a mystery. Also the width of the proton distribution is greater than expect. There should be a tighter correlation between θ_e and θ_p . There is some difference between the neutrons and protons that needs to be explained. The plot below shows the θ_{pq} distribution.

Fig 12. W^2 vs. θ_{pq} for neutrons (left) and protons (right). The upper limit on θ_{pq} appears to be too large. The title is wrong. These events do NOT have the cut1 cut on.

Click [here](#) to view the object (ROOT macro for fig 12) you uploaded.

Fig 13. The inadequate correlation of electron and neutron kinematics may be seen here. However, this is for two electron quantities!! The upper limit on theta_pq is the same as the previous figure - 12 deg.

Click [here](#) to view the object (ROOT macro for fig 14) you uploaded.

Reduce the upper limit on theta_pq from 12 deg to 8 deg and there is a small decrease in the low theta_p background and not much else.

Fig 14. Same as 11 with upper limit on theta_pq = 8 deg.

Click [here](#) to view the object (ROOT macro for fig 14) you uploaded.

Turn off the check_cuts and check_fiducial functions and get the following. Notice there appears to be a similar quasielastic band in the range theta_N = 60 deg -80 deg for both protons and neutrons. What creates the 60-deg neutron cutoff. Of course, this is all a bit backward since the problem with the GMn is too many neutrons at low Q2.

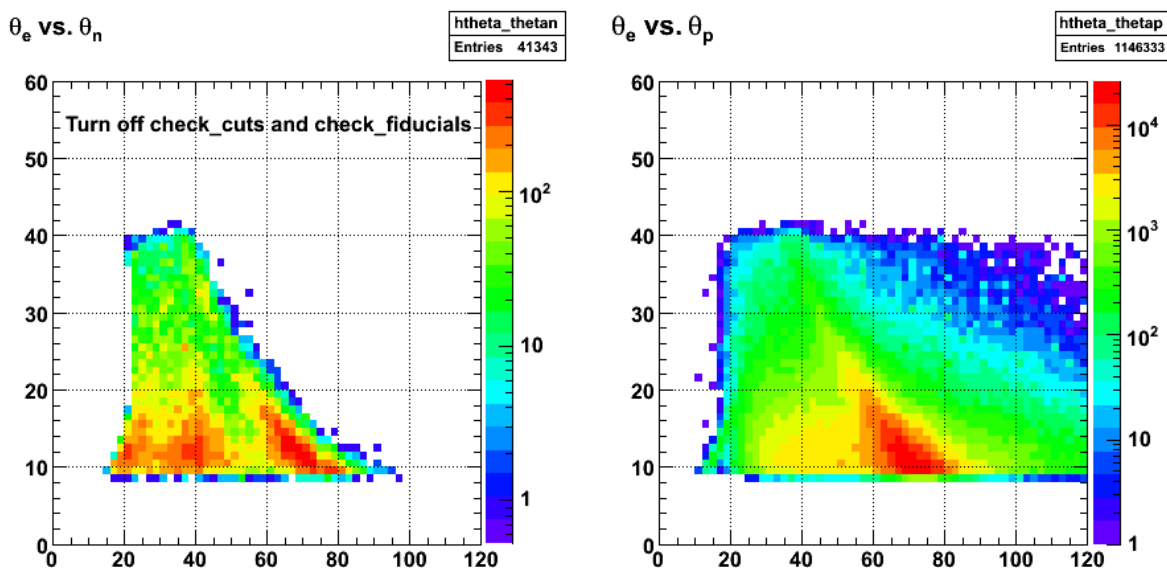

Fig 15. Same as Fig 14 except the check_cuts and check_fiducial tests are turned off.

Click [here](#) to view the object (ROOT macro for fig 15) you uploaded.

Now turn on JUST check_cuts_2250r. This makes it look like the 60-deg, neutron cutoff is in check_fiducials.

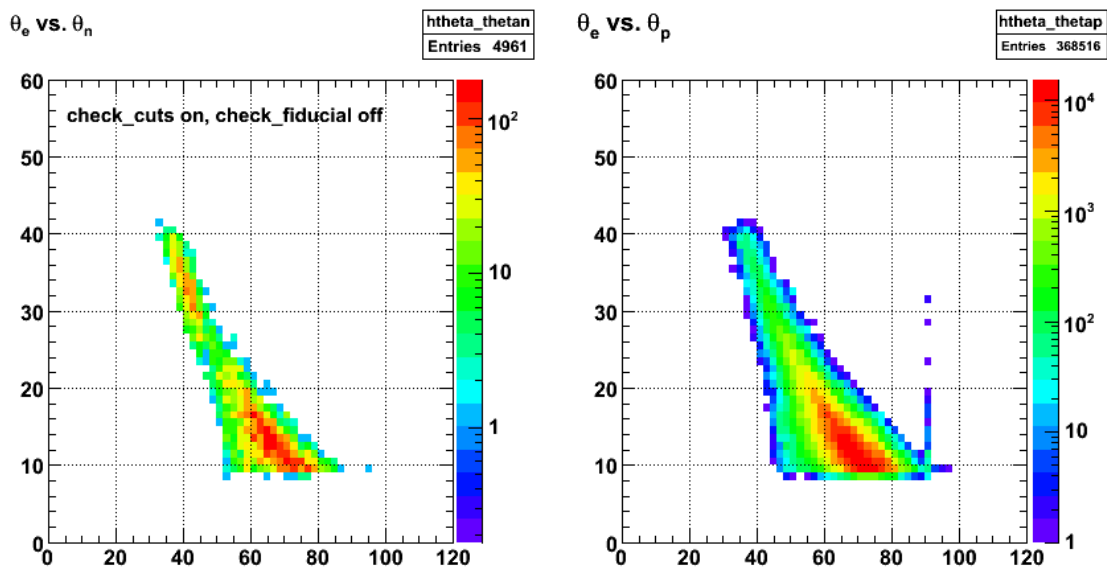

Fig 16. Same as Fig 15 with check_cuts turned on.

Click [here](#) to view the object (ROOT macro for fig 16) you uploaded.

Now turn off check_cuts and turn on check_fiducial. It looks like I can tighten up the theta_pq upper limit and the W2 cut.

Fig 17. W2 versus theta_pq for neutrons (left) and protons (right).

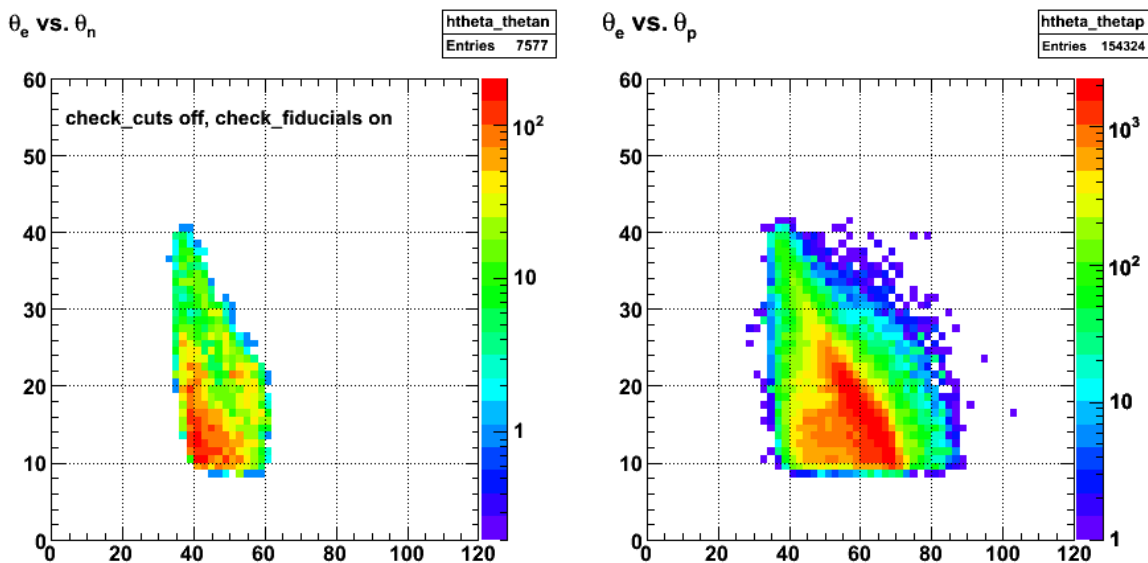

Fig 18. Same as fig 14-16 with check_cuts OFF and check_fiducials ON. The cutoff at neutron theta_pq ~ 60 deg is clear.

Jerry Gilfoyle's Enotebook page 206 - draft of E5 entry (gpg)

[Modified Thu May 8 16:37:00 2008 (GMT) gpg]

I have begun looking at the 2.6-GeV reversed field data. If you recall, in the last episode we had been faced with a low-Q2 explosion in the reduced GMn for $Q^2 < 0.5 \text{ GeV}^2$. This was shown by Jeff in [entry 375](#) and other places and I reproduce a version below in Fig 1 for the SC only and for now just two data runs (24519-24520).

2008-05-08 11:35:59

Fig 1. Reduced GMn for 2.6-GeV, reversed-field data for SC only.

All of the plots below are for SC data only, runs 24519-24520, 2.6-GeV, and reversed field. To understand what may be causing the rapid rise at low Q^2 , I began looking a variety of quantities. To check the θ_{pq} cut used to extract quasielastic events consider Fig 2. The left-hand-side shows W^2 versus θ_{pq} for neutrons with the maximum θ_{pq} set to 12 deg. This distribution looks reasonable. The right-hand-side shows the same distribution except for protons. Here it looks like there may be inelastic events leaking in at $\theta_{pq} = 8-12$ deg. Jeff has used a maximum of 6 deg for the higher Q^2 analysis ($Q^2 > 0.5 \text{ GeV}^2$) so I have lowered the maximum θ_{pq} to 8 deg.

Fig 2. W^2 versus θ_{pq} for neutrons (left) and protons (right).

Fig 3 shows the electron angle versus the nucleon angle for neutrons (left) and protons (right). The maximum θ_{pq} is 8 deg. The neutron distribution on the left-hand side has a mysterious cutoff at $\theta_n = 60$ deg that is not apparent in the proton distribution on the right-hand side. This is disturbing since both

distributions should cover the same kinematic range due to the acceptance matching. More below.

The proton distribution looks anomalously broad. This may be a result of a too-large, maximum theta_pq. I will investigate possibility that in a future entry.

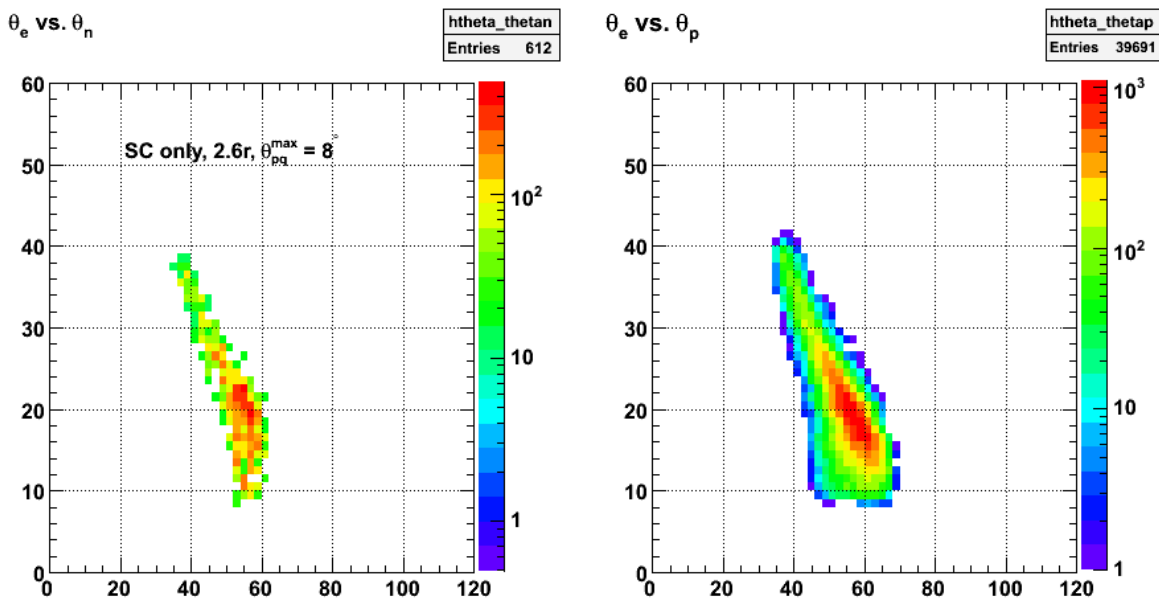

Fig 3. Electron angle versus nucleon angle for neutrons (left) and protons (right) for SC events, 2.6-GeV, reversed field data.

To investigate the mysterious cutoff in the neutron angle I turned some of the cuts off and redid the analysis. Fig 4 is the same as Fig 3, but I have turned off the function check_fiducial in Jeff's code. There are two important tests on the data in Jeff's code. The first is the function check_fiducial which does the acceptance matching and other stuff like tests for bad proton paddles in the SC, the track vertex position, and the number of photoelectrons. The second data test is the function check_cuts. This function checks that theta_pq is in the proper range and tests for bad wires, wrong neutron paddle, minimum neutron edep in the SC, ... The function check_cuts does the quasielastic selection. For Fig 4, check_cuts was turned on and check_fiducial was turned off.

The 60-deg cutoff in the neutron angle has disappeared and the neutron and proton distributions are, at least, qualitatively similar.

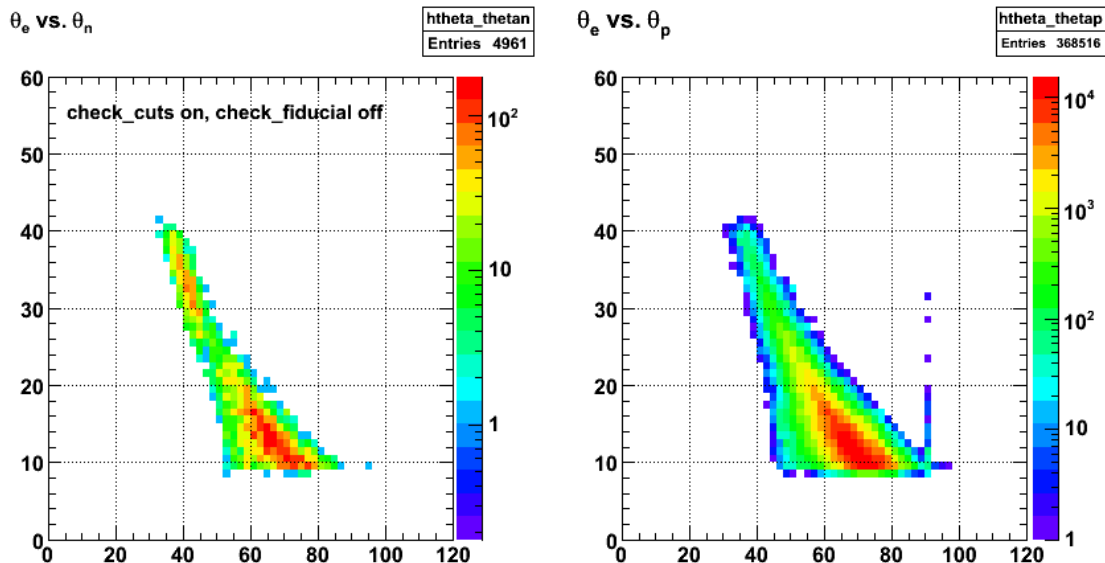

Fig 4. Same as Fig 3 with check_fiducials OFF and check_cuts ON.

To localize the problem more clearly I then turned check_cuts off and turned check_fiducials on. The results are shown in Fig 5 which is the same as Fig 4 with check_cuts now off and check_fiducials on. Since we no longer select quasielastic events, the distributions are not as well correlated, but the 60-deg cutoff in the neutron angle is apparent.

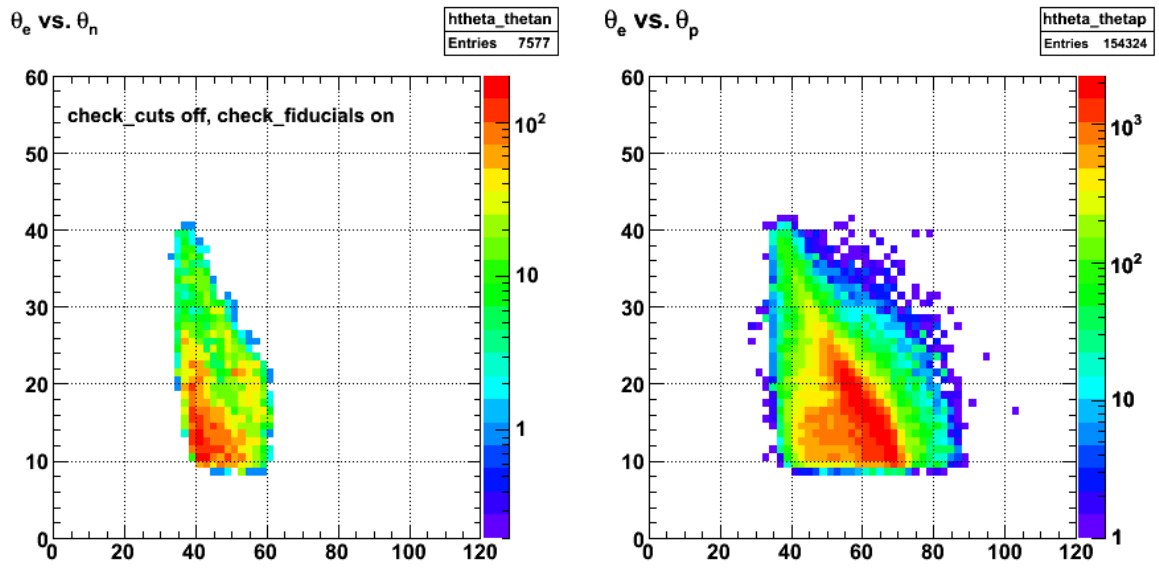

Fig 5. Same as Fig 3-4 with check_fiducials ON and check_cuts OFF.

Jerry Gilfoyle's Enotebook page 213 - Inelastic phi dependence (gpg)

[Modified Tue Jul 1 20:39:03 2008 (GMT) gpg]

Here is a log of the study of the phi dependence of inelastic events.
Response from Will to my email

Hi,

I'm in Chile. It's getting chilly here...

My gut instinct says the phi dependence you see is a large mistake in genev. I would look to see if you see anything like this in the data we already have. There should be a constant+sin(phi)+sin(2phi) dependence, or something like that, but I doubt it is such a sharp separation and I expect it is much less sharp at 11 GeV than at 4 GeV. I'm guessing they just did something very primitive in the event generator, for delta production.

If I'm wrong, and it's a real effect, then yes, I think it's something we should cut on.

For more input, you could ask the authors of genev, or turn off all except delta production, or ask Hovanes or Kyungseon.

Thanks,

- Will

Jerry Gilfoyle wrote:

> Hi Will,

>

> Hope things are going well in Chile or wherever you are at the moment. A few weeks ago I had a conversation with Bogdan Wojtsekhowski about the accuracy that we can measure R at the highest Q2 bin in the 12-GeV GMn proposal. For the requested running time we found (after my mistakes got corrected) that there will be about 500 events collected in the range Q2 -13-14 GeV2. Bogdan thinks it is unrealistic to expect we will be able to get adequate separation of the quasielastic (QE) and inelastic (IN) events in this last Q2 bin because the angular resolution for the neutrons limits our ability to use the theta_pq cut as effectively as we can for separating the QE and IN proton events. Also, we use a W2 cut (W2 < 1.2 GeV2) to get rid of additional IN events and at higher Q2 this cut will remove more and more QE events because the width of the QE peak increases. We all knew about this issues, but I have decided to take a closer look at them over the last few weeks with one of the undergrads working for me this summer.

> One of the ideas I had was based on something I saw last summer. We use the code GENEV to calculate the angles, energies, and topologies of the inelastic events. We use Jeff's QUEEG for the quasielastic events. The attached figure shows distributions of phi_pq versus theta_pq for the quasielastic events (left-hand panel), inelastic ones (middle panel), and the combined events (right-hand panel). For the QE events there is no dependence on phi_pq and most of them are at theta_pq < 1.5 deg. No surprise there. The interesting thing is the phi_pq dependence of the inelastic events. The spectrum is dominated by the two large lobes centered at phi_pq = ± 90 deg and reach a maximum width of about ± 30 deg. The plots are for the range Q2 = 6-7 GeV2. We started the study here just so we could check it against what we did last summer as a test. What the middle panel tells me is that we could use a cut on phi_pq, say ±(90 ± 20 deg) to reduce the inelastic background. We would lose some QE events, but the reduction in the IN background would be larger. My student is currently working on the Q2 = 13-14 GeV2 simulations. Anyway, I was wondering what you thought of this idea? Have you come across it before? In using the ratio method to measure GMn we've only used the theta_pq information because the QE events are independent of phi_pq. At the higher Q2, the inelastic dependence on phi_pq may give us another tool to reduce the background. Let me know what you think.

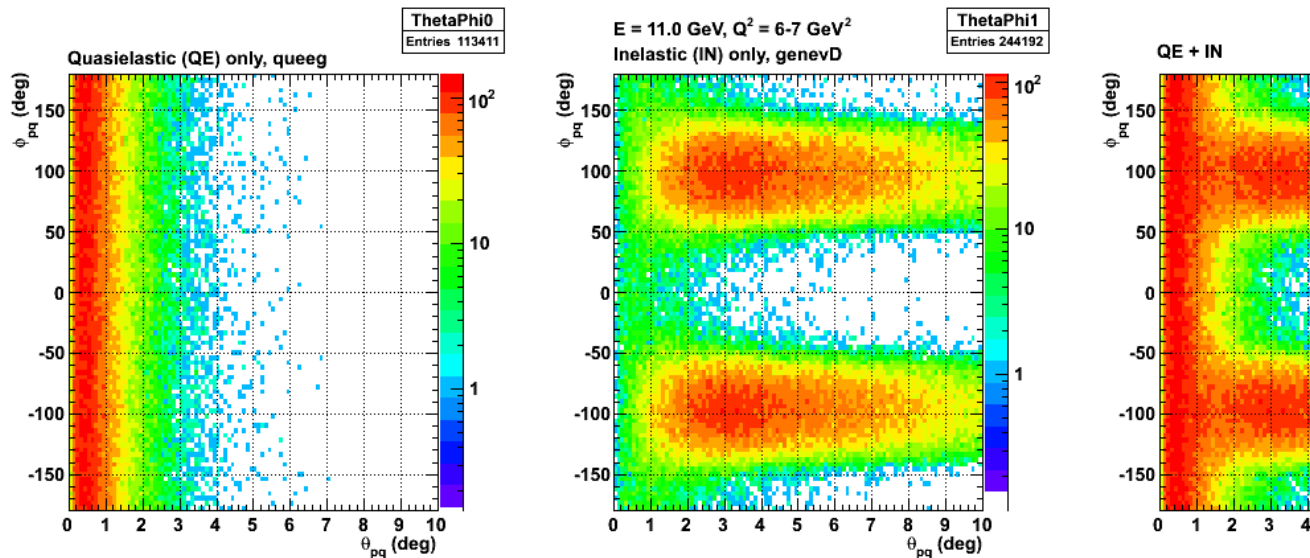

Fig 1. Plot I sent to Will.

Plot from a recent eod run for epn events with the QE cut ON. hmmm! try this with no QE or epn cuts.

2008-07-01 16:31:26

Jerry Gilfoyle's Enotebook page 215 - FastMC results for $Q^2 = 13-14 \text{ GeV}^2$ (gpg)

[Modified Thu Jul 10 16:26:14 2008 (GMT) gpg]

Below are results of Mark Moog's calculations for the 12-GeV GMn proposal in the range $Q^2 = 13-14 \text{ GeV}^2$, the highest Q^2 bin from the proposal.

Comparison of W^2 spectra for neutrons with different cuts for $Q^2 = 13-14 \text{ GeV}^2$.

Click [here](#) to view the object (ROOT macro for fig 1.) you uploaded.

For protons, it's more difficult because there are more inelastic protons finding their way in the W^2 spectra.

e singles

en coincidence

theta pq cut

theta pq + phi pq cut

Same as Figure 1, but for protons and the effect of the phi_pq cut is added.

Jerry Gilfoyle's Enotebook page 216 - Fermi Correction for CAN (gpg)

[Modified Mon Aug 18 02:04:02 2008 (GMT) gpg]

I first did the fermi correction calculation at 4 GeV to see if I got the same thing as JL in entry [398](#) in the E5 elog. For the following command,

```
nice /home/gilfoyle/gmn/ana.6GeV/bin/LinuxRHEL3/qe_ana -M 1000 -n 24023 -L -f /home/gilfoyle/gmn/run/simrun1.dat -r -a -v /home/gilfoyle/gmn/run/result1
```

I get the following result which is reasonably similar to JL's result (at least enough to go on to 2.6 GeV).

2008-07-13 23:54:22

Fig 1. Fermi correction for the EC at 4.2 GeV using the above command.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (Root histogram file for fig 8.) you uploaded.

I have started working on the Fermi correction calculations to finish off the analysis note. The first plot below shows the same calculation as shown in Fig 1 by Jeff. The plots are very similar, but the correction factor is higher at the low Q2 in Fig 2 than at the same Q2 in Fig 1. The difference between the smeared and unsmeared distributions is much the same.

Fig 2. Calculation of the Fermi correction to R for the 4.2-GeV data. Compare with Fig 1.

Difference between the Fermi correction to R for the smeared and unsmeared electron angle for the 4.2-GeV data.

The results for the 2.6-GeV data set are shown below. There are some significant differences between the ratio correction for the EC between the calculation in Fig 3, and the calculation in the analysis note (compare Fig 3 below with Fig 2.62 in the analysis note). This is under study. The effect of the electron angle smearing is again very small.

Fig 3. Fermi correction with and without smearing for 2.6 GeV, normal polarity data.

Fig 4. Difference between the ratio correction for EC neutrons with and without electron angle smearing for 2.6 GeV, normal polarity.

Numbers for 2.6n. Data are from Lachniet file for final results and difference between smeared and unsmeared 2.6n calculation are in the last column.

ROOT has an option for doing binomial statistics so use that and run it again. The spectrum for delta_R looks the same as before, but now the point at 0.8 GeV² now agrees with the other points!!!! All I did was change one of the options on two histograms??? I suspect that I may have had an indexing problem in Fig 5 above. After repeated simulations (see below) the difference between the smeared and unsmearred has gone away.

Click [here](#) to view the object (OOT histogram file for fig 7 for smeared analysis.) you uploaded.

Use [Bayesian errors](#) instead of binomial ones. Click [here](#) to view the object (ROOT macro for getting Bayesian uncertainties.) you uploaded. When I fit a constant using MINUIT to the difference between the smeared and unsmeared EC Fermi corrections, then I get a reduced chi-square of about one as expected. This is good though the uncertainties on the differences are now a mixture of Bayesian and Poisson statistics. The problem now is that the lowest Q2 point (where the Bayesian statistics have the greatest effect) is many standard deviations away from zero. I don't believe this is real since as I increase the throws in the simulation, that difference has been going down. Leave this as a mystery for now.

Jerry Gilfoyle's Enotebook page 218 - Final delta_R results for CAN (gpg)

[Modified Mon Aug 18 15:56:12 2008 (GMT) gpg]

The committee requested several plots related to the effect of the electron angular resolution as described in the excerpt from the final review below.

2. Before final approval he requested the following items.

2.a. The GSIM simulations of the measurement in entry 410 of the E5 elog should be added to the analysis note.

2.b. Fit the SC neutron detection efficiency in Fig 3 of entry 410 with a modified function (i.e. fewer terms in the polynomial) and calculate the SC Fermi correction.

2.c. Add the measured proton efficiency to the simulated one in Fig 1 of entry 410.

2.d. Calculate the Fermi correction for the 2.6-GeV data with the smeared electron angular resolution as we did for the 4.2-GeV data in Figure 1 of entry 398 in the E5 elog.

2.e. Take the difference between the Fermi corrections with unsmeared and smeared electron angles (see entry 398 and 2.d) as an additional systematic uncertainty. This result would be added in quadrature to the existing systematic uncertainty.

Below are the plots for the CAN to satisfy the committee on items 2d-2e.

Fig 5. Comparison of NDE from measurements (lhs) and GSIM (rhs) for 2.6n.

Click [here](#) to view the object (ROOT macro for Fig 5.) you uploaded.

The strange behavior of the Fermi correction for the GSIM calculation is due to wide variations in the scale factor from sector to sector and paddle to paddle. To smooth these out (and still be within the letter of the law of the final committee review) I used the summed NDE curve (Fig 3 of entry 410 in E5 elog) for all the GSIM NDE fits and obtained the following result which is much more reasonable than previous ones.

2008-08-25 10:37:07

Fig 6. 2.6n, GSIM Fermi correction with fixed GSIM NDE for all paddles and sectors. The parameter values were fixed at the best fit values.

Now let the parameters vary and fix the overall scale factor to 1.0 and things look consistent.

2008-08-25 10:48:20

Fig 7. Same as Fig 6 with all parameters varied except scale = 1.0.

Click [here](#) to view the object (ROOT macro for fig 7) you uploaded.

Now fix the coefficient for the 3rd order term to zero and fit the NDE spectrum.

2008-08-25 11:04:31

Fig 8. Same as fig 7 with the 3rd-order term coefficient set to zero in the fit.

Click [here](#) to view the object (ROOT macro for fig 8) you uploaded.

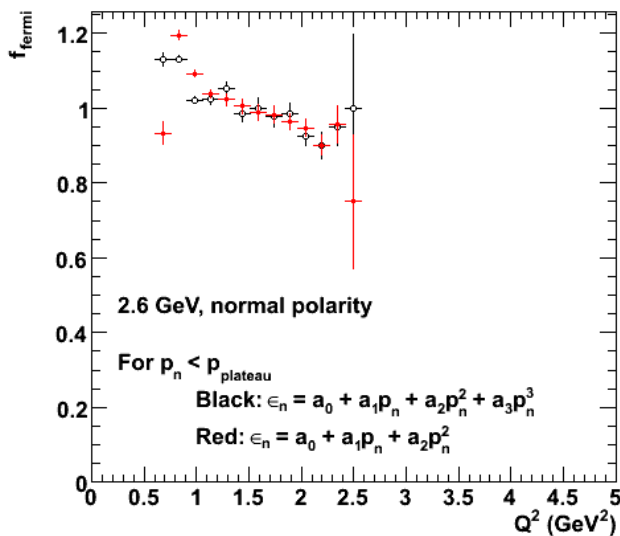

Fig 9. SC Fermi correction for 2.6n with third-order polynomial below the plateau in the SC NDE (black points) and for a second-order polynomial (red points).

Click [here](#) to view the object (ROOT macro changingPolynomial1.C for Fig 9) you uploaded.

The two calibration curves used in the Fermi correction calculation look like the following. One is a third-order polynomial with a plateau. The other is a second-order polynomial with a plateau. The third-order polynomial has a kink due to the dip in the SC NDE shown in Fig 10. This occurs at a neutron momentum of about $p_n = 0.9$ GeV/c which in quasielastic kinematics corresponds to Q^2 of around 0.7 GeV².

Jerry Gilfoyle's Enotebook page 221 - Impact of theta_pq cut (Jerry Gilfoyle)

[Modified Wed May 27 03:47:50 2009 (GMT) Jerry Gilfoyle]

To answer the question raised by Sebastian Kuhn on the effectiveness of the theta_pq cut for the E5 analysis I made some calculations of the W2 spectra using the QUEEG/GENEV event generator. The plots below are for the output of the event generator and have not been processed through GSIM.

2008-08-29 21:53:08

Fig 1. W2 spectrum for ep events for 4.2 GeV.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

Click [here](#) to view the object (Tared, gsipped, ROOT histogram files for fig 1) you uploaded.

2008-08-29 22:03:05

Same as Fig 1 for neutrons

Click [here](#) to view the object (ROOT macro for fig 2) you uploaded.

Now get the W2 spectrum for protons and neutrons for all Q^2 and 4.2 GeV using the different theta_pq cut for different Q^2 bins. See log got 9/1/08. The ratio of QE:IN is 1:1.

W² for ep Events

Jerry Gilfoyle's Enotebook page 222 - Selecting Quasielastic events. (Jerry Gilfoyle)

[Modified Tue Sep 2 14:52:57 2008 (GMT) Jerry Gilfoyle]

The first plot shows the effect of the theta_pq cut on the 4.2-GeV, ep data. To make an estimate of the inelastic background in the quasielastic region we have run the QUEEG/GENEV event generator and obtained the following results.

Fig 1. Measured W^2 spectrum for 4.2-GeV ep events for ep events with the theta_pq cut on and off.

We adjusted the relative amounts of quasielastic (QE) and inelastic (IN) to be consistent with the measured W^2 spectrum in Fig 1. The spectra here are more narrow than the measured ones, but they do not include the CLAS resolution and other effects.

Fig 2. Simulated W^2 spectrum for 4.2-GeV ep events for ep events (left-hand panel) and en events (right-hand panel).

Now turn on the theta_pq cut. The cut used in the analysis is different for different Q2 bins. The maximum theta_pq cuts used are listed below.

Q2 range	maximum theta_pq
1.0-1.5	4.5
1.5-2.0	4.0
2.0-2.5	3.5
2.5-3.0	3.0
3.0-4.5	2.5

Jerry Gilfoyle's Enotebook page 234 - Dsim plots for $Q^2=1.75-2.25$ GeV² (gpg)

[Modified Fri Jan 16 23:26:37 2009 (GMT) gpg]

Plots below will be used for CLAS Note. First set shows Q^2 distribution for summed PART bank (left), summed genevD PART bank (middle), and summed queeg PART bank (right). Why is there a high Q^2 tail on the queeg results?

fig 1. Comparison of Q^2 distributions for summed PART bank (left), summed genevD PART bank (middle), and summed queeg PART bank (right).

It appears QUEEG does not use the upper limit on the electron scattering angle in selecting that quantity. I modified the code to look like the following in the function `Jqe_ana_calc::get_electron_angle` in the file `Jqe_ana_calc.cpp`.

```

if(htype == NEUTRON){
  e_axis = neutron_restframe_xsec->GetXaxis();
  ebin = e_axis->FindBin(E_rf);
  projy = neutron_restframe_xsec->ProjectionY("", ebin, ebin);
  // gpg. add code here to put upper limit on electron angle.
  while(angle > theta_max_rf){
    angle = projy->GetRandom();
  }
  //cout << "e-n, electron angle=" << angle << endl;
} else if(htype == PROTON){
  e_axis = proton_restframe_xsec->GetXaxis();
  ebin = e_axis->FindBin(E_rf);
  projy = proton_restframe_xsec->ProjectionY("", ebin, ebin);
  icounter = 0;
  // gpg. add code here to put upper limit on electron angle.
  while(angle > theta_max_rf){
    angle = projy->GetRandom();
    icounter++;
  }
  //cout << "e-p, electron angle=" << angle << " E_rf=" << E_rf << " counter=" << icounter << endl;
} else{
  angle = 0;
}

```

Click [here](#) to view the object (tarred, gzipped archive for fig 1.) you uploaded.

Jerry Gilfoyle's Enotebook page 236 - Checking Dsim with 4.2 GeV data (gpg)

[Modified Fri Jan 23 19:16:53 2009 (GMT) gpg]

Generate some spectra from the 4.2 GeV E5 data for comparison with Dsim results. Initially things look quite bad. See JL figure in the PAC32 talk and compare plots of ep W2 spectra. My spectra have many more inelastic events; the delta peak is washed out and the QE peak has lots of background. Turning on the theta_pq cut improves things, but it still looks weird. See fig 2 below. The first plot shows the proton mass spectrum. I think I need a cut here to clean things up.

2009-01-21 00:07:45

Fig 1. Proton mass spectrum. See log-09-jan-20 for more details.

Check the proton mass.

2009-01-21 10:00:06

Fig 2. Proton mass calculated from the measured momentum and beta for 4.2 GeV.

Click [here](#) to view the object (ROOT macro) you uploaded.

Turn on cut on proton mass and there is little improvement. I notice the following plot. Why is there such a high threshold on Q2 in the QE region?

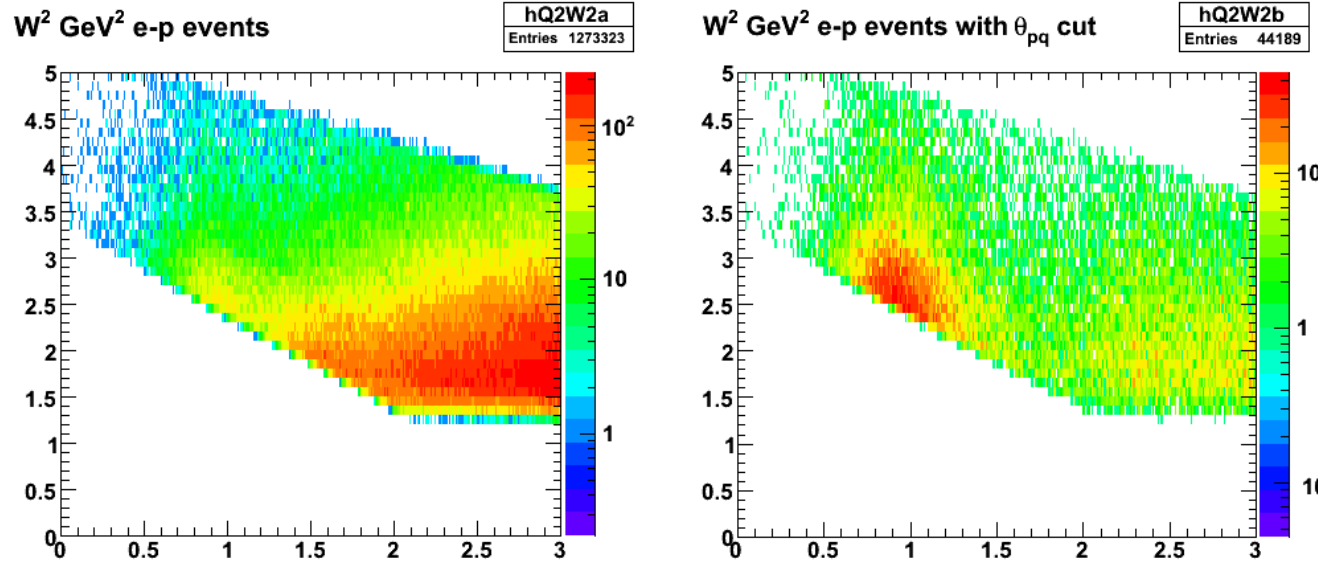

Fig 3. Q2 vs. W2 for 4.2 GeV.

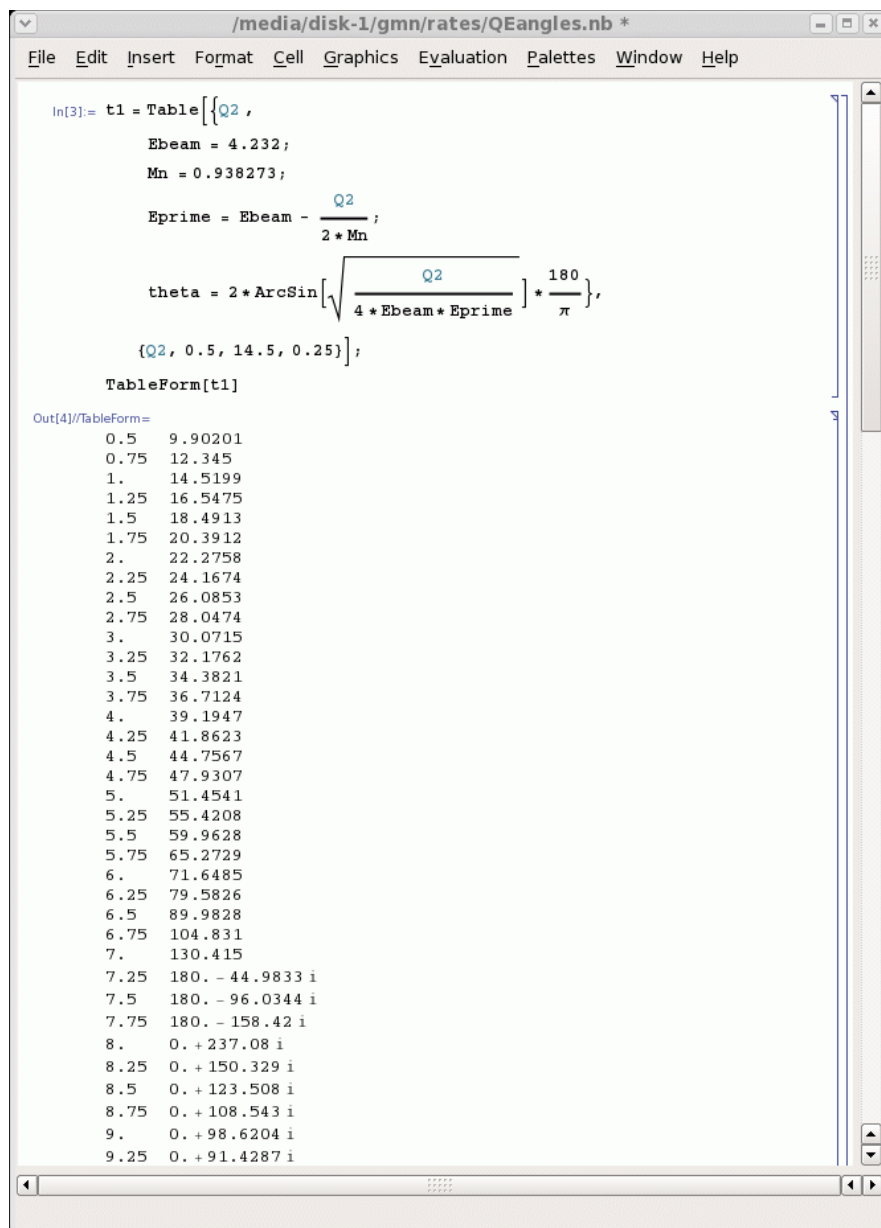

Fig 4. Mathematica calculation of Q2 and minimum angle. Shows that for 4.2 GeV and a minimum CLAS angle of about 10 deg, we should see QE events at much lower Q2.

Turn off efits and things work! I reproduce the shape of JL's thesis plot.

Fig 5. W^2 for ep events with θ_{pq} cut off (left) and on (right). The shape agrees with JL, but I have many fewer events???

Compare the PART bank dsim with the 4.2-GeV E5 data. The PART bank is much narrower because it doesn't have the detector resolution. It looks like there may be too much delta and not enough of the higher mass resonances in gennev, but that is a detail I don't think I have time to worry about.

Fig. 8. Compare the PART bank dsim with the 4.2-GeV E5 data.

Jerry Gilfoyle's Enotebook page 237 - Phi_pq dependence of inelastic events (gpg)

[Modified Fri Jan 23 19:27:18 2009 (GMT) gpg]

I saw something last summer in the phi_pq dependence of the inelastic events when Mark Moog was working on the gmn12 simulations. In genev, there appeared to be a strong phi dependence to the inelastic events that I thought could be exploited to reduce the inelastic backgrounds. I mentioned this to wkb who thought it was likely to be a mistake. Having the E5, 4.2 GeV data in hand at the moment I took a look. See the figure below. The middle panel shows results from Dsim. There are some clear peaks in the phi_pq dependence at +/- 90 deg and their theta_pq angular distribution extends down inside the theta_pq cut. Thus, we would be able to put phi_pq cuts on the data to reduce the inelastic contamination of the quasielastic peak.

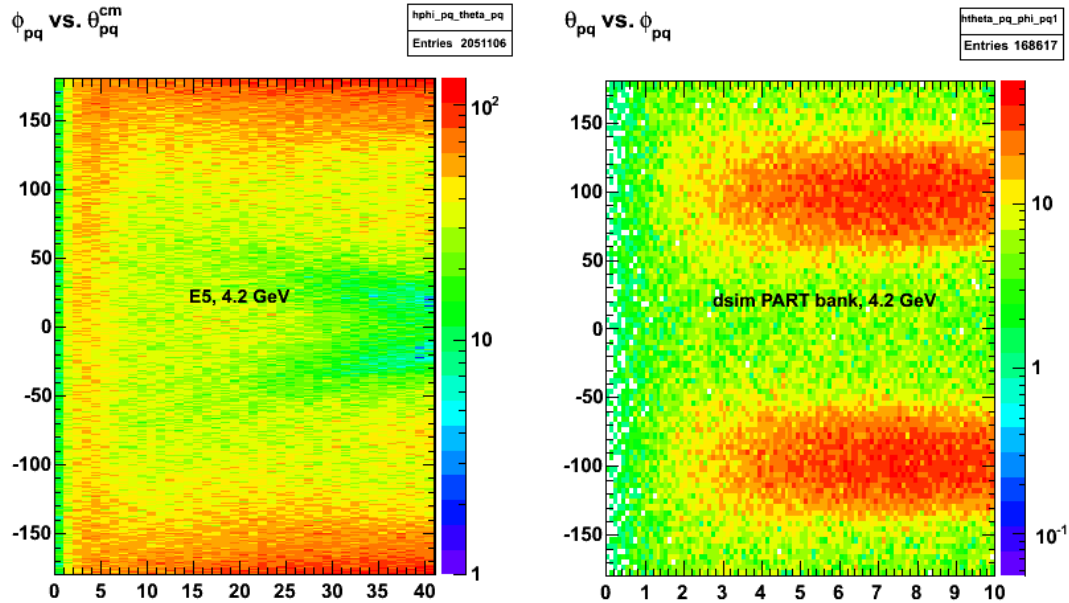

Fig 1. Comparison of phi_pq vs theta_pq of the E5, 4.2-GeV data (left panel) and Dsim at 4.2 GeV (middle panel). The label on the middle panel is backwards. It is really phi_pq vs. theta_pq.

Click [here](#) to view the object (ROOT macro) you uploaded.

The data also show a clear phi dependence, but it's way different from genev. I don't understand this difference, but we clearly see a phi_pq peak in the inelastics at 180 deg. Add cut on phi_pq to 4.2-GeV analysis and get the following curve; not much of an improvement at a cost of losing about half the events.

Fig 2. Comparison of W2 spectra with 'standard' cuts (no fids) and with added phi_pq cut (-90 deg < phi_pq < 90 deg).

Jerry Gilfoyle's Enotebook page 241 - Jerry Miller email (Jerry Gilfoyle)

[Modified Thu May 21 22:22:55 2009 (GMT) Jerry Gilfoyle]

Plots and fits for GMn for Jerry Miller.

Fig 1. Simple polynomial fit to CLAS GMn data.

Click [here](#) to view the object (ROOT macro for fig 1) you uploaded.

The reduced chisquare is large for the fit above. Add the systematic and statistical errors in quadrature and the reduced chisquare is now too small. This is not unexpected since the systematic uncertainties include effects (i.e. the proton cross section uncertainty) that are really scale uncertainties and would move the entire data set up or down together and other uncertainties which are point-to-point variations like the NDE which vary significantly from one Q^2 to the next. Adding the systematic uncertainties to the statistical ones in quadrature is only partially correct (and partially wrong).

Fig 2. Simple polynomial fit to CLAS GMn data with systematic and statistical uncertainties added in quadrature. Note the good agreement between the parameters for the fits in figs 1-2.

Choosing the order of the polynomial. Using a second order polynomial achieves an adequate reduced chisquare and is appropriately smooth over the Q^2 range of the data. Adding more terms improves the reduced chisquare, but I start getting variations in the curves that are not smooth enough.

statistical uncertainties only.

order of polunomial	chi2/ndf
0	73/25
1	57/24
2	52/23
3	52/22
4	50/21
5	36/20
6	36/19
7	35/18
8	30/17

add statistical and systematic errors in quadrature and refit.

order of polunomial	chi2/ndf

Are the CLAS GMn results consistent with the dipole? Yes. See plots below.

Fig 3. CLAS GMn results are consistent with $G_M^n = \mu_n G_D$.

Fig 4. CLAS GMn results are consistent with $G_M^n = \mu_n G_D$ within the 2% systematic error.

Jerry Miller email below.

Jerry, I do need such an analytic fit. However, while your fit goes through the data points, it will have a huge effect on my results, for probably spurious reasons. your fit for GMn goes to a constant at very large Q2. This means a delta function charge density at the origin. You can get an equally good fit, that assumes the asymptotic quark counting form by using Kelly's formula which is almost as simple as yours. an even simpler interpretation of your data would be to use a dipole. this would make the neutron charge density more negative at the center. i will take a look at your paper as soon as i can.

jerry

* Simple parametrization of nucleon form factors.*
 J.J. Kelly (Maryland U.) . Dec 2004.
 Published in *Phys.Rev.C70:068202,2004*.

First make a plot of the Kelly parameterization of GMn and compare with the CLAS data.

gmn1

fig 5. Comparison of of the Kelly parameterization of GMn and the CLAS data.

Click [here](#) to view the object (Root macro) you uploaded.

Root code used for above plot of Kelly parameterization.

```
// Macro kelly1.C
Double_t gmn1(Double_t *x, Double_t *par)
```

```

{
  float Mp=0.938, mun=1.91;
  float_t xx =x[0];
  float tau=xx/(4*pow(Mp,2));
  Double_t f = pow(1+(xx/0.71),2)*(par[0] + par[1]*tau)/(1 + par[2]*tau + par[3]*pow(tau,2) + par[4]*pow(tau,3));
  return f;
}
void gmn1plot()
{
  TF1 *f1 = new TF1("f1",gmn1,0.01,60,5);
  f1->SetParameters(1.0,2.33,14.72,24.20,84.1);
  f1->GetYaxis()->SetTitle("G_M^{n}/\mu_n");
  f1->GetXaxis()->SetTitle("Q^2 (GeV^2)");
  f1->SetMinimum(0.4);
  f1->Draw();
}

```

Now use the same function in the Kelly parameterization on the CLAS data.

gmn1

Fig 2.5 p_m for 2.6r. What is up wit dis????!!!! See stuff below.

Checking queeg.

2.6 Nucleon momentum distribution for 2.6r with Fermi motion turned on in the cm frame.

Fig. 2.7 - Nucleon momentum distribution for 2.6r with Fermi motion turned on in the lab frame.

Checking queeg. Plots below are for pfermi=0.0.

2009-06-24 09:04:08

Fig 3. Nucleon momentum in the CM frame.

2009-06-24 09:20:53

Fig 4. Nucleon momentum in the LAB frame.

Checking eod5c.C. It turns out the problem was that I had added some neutron analysis (ed2en) to study some GMn related issues and that was mucking up the p_m spectrum. I haven't figured out the details yet, but turning off the ed2en function gives me the following results for p_m .

Fig 5. Corrected p_m distribution for 2.6r.

Fig 7. Check on ALTp.

```

Jerry Gilfoyle's Enotebook page 245 - First study of neutron efficiency in CLAS12 TOF (gpg)

[Modified Wed Aug 5 02:10:27 2009 (GMT) gpg]

Socrat was modified to produce a histogram file containing histograms of the neutron momentum calculated from the electron information and assuming elastic scattering. Electrons were randomly distributed in the range $\theta_e = 20\text{-}30$ deg with energies appropriate for 11-GeV electrons scattering from neutrons. No attempt was made to consider the Fermi motion. There are just two histograms in the file each with different requirements. Below is a plot of the neutron momentum distribution for found events (black) and reconstructed ones (red). Found here means an event where forward tracking was successful (ForwardTrack=1) so we have a good electron. Reconstructed here means we have a good electron AND a hit in the otopf1a that is within 10 deg of the direction expected for the neutron based on the electron information. Based on 5000 thrown events.

2009-07-21 00:04:34

Fig 1. Momentum spectrum of found neutrons (black) and reconstructed ones (red). The rapid changes in the reconstructed neutron momentum are puzzling!!

Sebastien notices that the magnetic field maps were not being read in correctly. Now the plot looks like this.

2009-07-24 15:47:37

Fig 2. After redoing the analysis with the right magnetic field files.

Why is there a bin with more reconstructed than found neutrons??? Why are there so many reconstructed neutrons relative to the found ones. From CLAS6, we only expect about 8-10% efficiency.

Effect of reading in the correct magnetic field map.

Fig 3. Momentum resolution from Socrat with the correct magnetic field. using the command T->Draw("(r_p[0]-g_p[0])/g_p[0]","abs(r_p[0]-g_p[0])/g_p[0]<1")

Fig 4. Momentum distribution with the wrong magnetic field map.

Fix the identification of found neutrons by identifying events where the predicted neutron position (derived from the electron information only) lies within the face of OTOFP1A.

2009-07-27 19:15:15

Fig 4. Corrected neutron momentum spectra. For elastic e-n scattering with $\theta_e = 20-30$ deg and $E_{beam}=11$ GeV.

Fig 14. Final (?) results for tuning the W range.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The W spectrum for choosing the W range. I think we can simply say, we picked the central region of the pick going about halfway down each side (to zero on the low- W side and the dip on the high- W side). Setting the W value is certain within about 10% so Matt's results are fine. The wide W range shown here is just too wide even by eye.

2009-08-14 19:22:41
Fig 15. W spectrum showing the position of the W limits. Histogram file is the same as figure 14.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now try shrinking the W range a bit to see what happens. It looks like the statistics are a big effect here. Use Matt's results.

2009-08-14 23:50:00

Jerry Gilfoyle's Enotebook page 249 - Final(?) results for Calina cut for 2.6r (gpg)

[Modified Thu Sep 10 22:36:21 2009 (GMT) gpg]

The results below are based on GSIM results stored in eod/sim/calina/.

Fig 1. GSIM results for runs 1-12.

Click [here](#) to view the object (sumsim.C root macro for fig 1. Stored in eod/sim/calina/analysis.) you uploaded.

I did some more runs and modified the scripts to run two jobs per node to take advantage of the dual CPUs. This did NOT increase the run time for each calculation.

Fig 2. Updated version of fig 1 (runs 1-22).

Click [here](#) to view the object (ROOT macro) you uploaded.

Jerry Gilfoyle's Enotebook page 250 - Checking 2.6n ALTp MM2 and W cut and uncertainties (gpg)

[Modified Fri Sep 4 15:03:27 2009 (GMT) gpg]

First get the systematic uncertainty due to the quasielastic cut. See the Mathematica notebook eod/uncs/ALTpUncertainties26n.nb for the final results.

2009-08-30 10:41:03

Fig 1. Comparison of 2.6n ALTp for systematic uncertainty of QE cut.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now test the MM^2 cut used to select the neutron in the final state.

2009-08-30 15:16:39

Fig 2. Comparison of ALTp with different MM^2 cuts.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

2009-08-30 19:51:01

Fig 3. Effect of lowering the lower limit on MM2 cut.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

2009-08-31 12:42:50

Fig 4. Test new wider range for the MM2 cut. Note the lower limit on the Black MM2 is WRONG! It should be 0.83 GeV².

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Fig 5. Test new upper limit on MM2 cut.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The last two plots show little difference between ALTp for MM2 < 0.97 GeV2 or MM2 < 0.94 GeV2 so pick MM2 < 0.97 GeV2.

Fig 6. MM2 plot showing new MM2 cut (MM2 = 0.75-0.97 GeV2) and fit used to determine the centroid of the peak.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Now shrink the size of the MM2 cut by 10% and get the systematic uncertainty.

2009-08-31 16:59:53

Fig 7. Comparison of ALTP with MM2 shrunk by 10% to get the change used for the systematic uncertainty (blue points).

fSumw[4]=-0.00266462, x=0.175, error=0.0149186
fSumw[5]=0.00133526, x=0.225, error=0.0255873
fSumw[6]=0.00412141, x=0.275, error=0.0271704
fSumw[7]=0.00205137, x=0.35, error=0.0327671
fSumw[8]=0.000832865, x=0.5, error=0.036392
fSumw[9]=0.00086749, x=0.65, error=0.0319774
fSumw[10]=-0.00430327, x=0.85, error=0.030909
fSumw[11]=0.0043112, x=1.25, error=0.0544894
fSumw[12]=0.00637105, x=1.75, error=0.199317
```

```
fSumw[13]=0, x=2.08333, error=0
root [44]
```

Now study the effect of increasing the width of the W cut by 10%.

2009-09-01 09:55:52

Fig 11. Effect of increasing the width of the W cut by 10%.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

The difference between the two extractions of ALTP.

```
root [46] h12diff->Print("all")
TH1.Print Name = h12diff, Entries= 727, Total sum= -0.0370267
fSumw[0]=0, x=-0.0833333, error=0
fSumw[1]=0.000323651, x=0.025, error=0.00384308
fSumw[2]=-0.000157504, x=0.075, error=0.00367358
fSumw[3]=0.000984767, x=0.125, error=0.00729457
fSumw[4]=0.000814839, x=0.175, error=0.01446
fSumw[5]=-0.00629463, x=0.225, error=0.0248252
fSumw[6]=0.0009482, x=0.275, error=0.026402
fSumw[7]=-0.013727, x=0.35, error=0.0318571
fSumw[8]=0.00224737, x=0.5, error=0.0355519
fSumw[9]=0.000955978, x=0.65, error=0.0311939
fSumw[10]=0.00597822, x=0.85, error=0.0300711
fSumw[11]=0.00745918, x=1.25, error=0.0529804
fSumw[12]=-0.0365597, x=1.75, error=0.194492
fSumw[13]=0, x=2.08333, error=0
```

I suspect the large difference between the default value for ALTP and the value after increasing the width of the W cut seen in Fig 11 for x=0.225 is a fluctuation so I will decrease the width of the W cut and average the two results.

2009-09-01 11:28:51

Fig 12. Comparison of default ALTp at 2.6n with width of W cut decreased by 10%.

Jerry Gilfoyle's Enotebook page 251 - Uncertainties for 2.6n ALTp (gpg)

[Modified Fri Sep 4 15:02:34 2009 (GMT) gpg]

Investigate the systematic uncertainties associated with the cuts used to select epn events for the 2.6-GeV, normal-torus-polarity data. See the Mathematica notebook eod/uncs/ALTpUncertainties26n.nb for the final results. Cuts studied are the following.

```
table 7: photoelectron > 0
table 6: electron trk fid > 0
table 5: electron EC fid = 0 table refer to MJ's Mathematica notebook for 2.6r
table 4: egiyan thresold = 0
table 3: target wall
```

```
if (epn_event &&
    target_walls_ep &&
    quasielastic_cut &&
    //good_electron_fiducial &&
    //good_proton_fiducial &&
    good_egiyan_threshold &&
    good_electron_EC_fiducial &&
    good_electron_EC_trk_coords_fiducial &&
    //good_sampling_fraction &&
    good_photoelectrons) {
```

2009-09-01 13:49:44

Fig 1. Effect of Egiyan cut: none. All the points are exactly the same with the egiyan threshold set at 708 (default) or 778 (expanded).

Click [here](#) to view the object (ROOT histogram file) you uploaded.

2009-09-02 10:05:23
 Fig 2. Difference between default ALTP at 2.6n and +/- 10% change in EC track fiducial. Compare with fig 1.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The effect of reducing the size of the EC track coordinate cut for the 5th data point (pm=0.275 GeV/c) is pronounced. Checking the cut on the EC track coordinate.

2009-09-02 12:04:49

Fig 3. Default spectrum of EC_fiducial_cut - EC track coordinate.

2009-09-02 12:27:50

Fig 4. Turned off EC fiducial cuts and get much the same thing.

2009-09-02 12:41:13

Fig 5. Same as Fig 4, but now use 90% of the EC_fiducial_cut value. Not much change.

2009-09-02 13:27:44

Fig 6. Difference between default EC track coordinate cut and 90% value cut.

2009-09-02 13:31:48
 Fig 7. Same as fig 6, but divided by the default histogram for hp_m_unwghtplus4.

There appears to be no obvious problems with that bin so get the uncertainty by taking the difference between the values for ALTp and dividing by two. Now investigate the effect of the EC sampling fraction and changing its width by +/- 10%.

2009-09-03 11:22:08

Jerry Gilfoyle's Enotebook page 256 - Systematic uncertainties on ALTp for 2.6r data for EC_{etot} and EC pion threshold. (gpg)

[Modified Sun Sep 6 23:05:59 2009 (GMT) gpg]

Now do the systematic uncertainties on ALTp for 2.6r data for EC_{etot} and EC pion threshold using the +/- 10% method.

2009-09-05 21:02:47
Fig 1. Systematic uncertainty on the EC_{etot} cut (i.e., the sampling fraction).

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Get the systematic uncertainty by calculating $dALTp = (ALTp(90\% \text{ of cut}) - ALTp(110\% \text{ of cut}))/2$.

2009-09-05 21:06:24
Fig 2. Plot of differences divided by two from fig 1 for 2.6r. The label on the plot is WRONG!!!

Click [here](#) to view the object (Root macro) you uploaded.

TH1.Print Name = h12diff, Entries= 709, Total sum= 0.0170277
 fSumw[0]=0, x=-0.0833333, error=0

```
fSumw[1]=0.000103621, x=0.025, error=0.000659424
fSumw[2]=8.90847e-05, x=0.075, error=0.000594029
fSumw[3]=0.000297173, x=0.125, error=0.00107925
fSumw[4]=-0.000593074, x=0.175, error=0.00208806
fSumw[5]=0.00101165, x=0.225, error=0.00346466
fSumw[6]=-1.69771e-05, x=0.275, error=0.00360403
fSumw[7]=0.00150222, x=0.35, error=0.00507999
fSumw[8]=-0.00102033, x=0.5, error=0.00716573
fSumw[9]=0.000570933, x=0.65, error=0.0093646
fSumw[10]=0.00641637, x=0.85, error=0.0152564
fSumw[11]=0.00866699, x=1.25, error=0.0422658
fSumw[12]=0, x=1.75, error=0.278877
fSumw[13]=0, x=2.08333, error=0
root [69]
```

Now do the EC pion threshold cut.

2009-09-05 23:33:31

Fig 3. ALTP for variation in EC pion threshold of +/- 10% for 2.6r.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now get the difference between the different values of the EC pion threshold.

2009-09-05 23:38:28

Fig 4. Difference for fig3.

Click [here](#) to view the object (Root macro) you uploaded.

```

TH1.Print Name = h12diff, Entries= -20, Total sum= 0.000202318
fSumw[0]=0, x=-0.0833333, error=0
fSumw[1]=5.53815e-06, x=0.025, error=0.000655673
fSumw[2]=-8.06563e-06, x=0.075, error=0.000590844
fSumw[3]=1.55158e-06, x=0.125, error=0.00107358
fSumw[4]=-4.05032e-06, x=0.175, error=0.00207353
fSumw[5]=3.1855e-05, x=0.225, error=0.00343957
fSumw[6]=-2.31666e-06, x=0.275, error=0.00358083
fSumw[7]=-2.94212e-05, x=0.35, error=0.00504912
fSumw[8]=-4.09745e-05, x=0.5, error=0.00713307
fSumw[9]=0, x=0.65, error=0.00933891
fSumw[10]=0.000248201, x=0.85, error=0.0151978
fSumw[11]=0, x=1.25, error=0.0421989
fSumw[12]=0, x=1.75, error=0.278877
fSumw[13]=0, x=2.08333, error=0

```

The size of the effect of changing the EC pion threshold for the 2.6r data is much less than for the 2.6n data. Just as a quick check I increase the upper limit on the cut by 100% (instead of the usual 10%). I get a large (though not a factor 10) increase in the difference between the 90% value and the 200% value. Seems to be ok.

2009-09-06 19:01:20

Jerry Gilfoyle's Enotebook page 257 - Comparing ALTp with different MM2 cuts (gpg)

[Modified Fri Sep 11 18:38:24 2009 (GMT) gpg]

The magnitude of the dip in ALTp for the 2.6r data set is significantly shallower using the 2.6n cuts than it was before. The biggest difference appears to be the MM2 cut to select neutrons in the final state. The W cut to select QE events is nearly the same for both data sets (0.91-0.99 GeV for 2.6n and 0.92-1.0 GeV for 2.6r). Compare the MM2 distributions for each data.

For the 2.6n data.

2009-09-06 20:57:08

Fig 1. 2.6n MM2 distribution: red lines are the cut used in the analysis, blue lines are the previous 2.6r limits, and the black curve is a fit used to find the peak which is 0.88 GeV² as expected.

Click [here](#) to view the object (Root macro) you uploaded.

For the 2.6r data.

2009-09-06 21:20:28

Fig 2. 2.6r Results for a fit centered on MM2 = 0.87 GeV² instead of 0.88 GeV² because that is the peak of the neutron distribution. The fit range is 0.82-0.92 (not 0.92-0.92).

Click [here](#) to view the object (Root macro) you uploaded.

Now test ALTp for different MM2 ranges. First do 2.6r data. The statistical significance is poor, but the dip in ALTp pretty clearly goes away outside the central MM2 region.

2009-09-08 13:54:58

Fig 3. Comparison of ALTp for the 2.6r data and different ranges of the MM2 cuts used to select neutrons in the final state.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Now do the 2.6n data. The statistics are again lousy outside the central region. The dip may be diminished outside the central region, but we can't tell with these statistics. Note that the range used for the MM2 for the 2.6n data in Fig 4. was $0.83 < MM^2 < 0.91 \text{ GeV}^2$ which is centered on the MM2 peak for the 2.6r data, but is NOT centered on the MM2 for the 2.6n data. Redo the analysis below with $0.84 < MM^2 < 0.92 \text{ GeV}^2$.

2009-09-08 21:11:50

Fig 4. Comparison of ALTp for the 2.6n data and different ranges of the MM2 cuts used to select neutrons in the final state.

2009-09-09 14:02:25

Fig 5. Comparison of ALTP for the 2.6n data and different ranges of the MM2 cuts used to select neutrons in the final state with the range on the MM2 cuts shifted up by 0.01 GeV2 so the 2.6n central region is symmetric about the MM2 peak. Done with with 0.84 < MM2 < 0.92 GeV2.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Note the significant change in the magnitude of the dip just by shifting the position of the MM2 cut up by a small amount. The cut went from 0.83 < MM2 < 0.91 GeV2 to 0.84 < MM2 < 0.92 GeV2. This is odd especially since I showed in previous entries that the magnitude was fairly robust to large changes in the limits of the MM2. The difference here is that the magnitude of the dip in those studies was about 0.05 which is about the value for the range 0.84 < MM2 < 0.92 GeV2 while the magnitude is about 0.07 for the range 0.83 < MM2 < 0.91 GeV2. Perhaps this large magnitude is a fluke. Apply the +/- 10% method to the uncertainty in this cut to see what happens.

2009-09-09 22:04:33

Jerry Gilfoyle's Enotebook page 258 - Changes to gsim scripts (gp)

[Modified Tue Sep 8 18:37:55 2009 (GMT) gp]

I have changed the scripts for Calina's gsim calculations so that the submit_eod.pl scripts will submit two jobs to each node (one per CPU) so we can take advantage of each CPU. The plot below shows ALTp calculated with this new script. Within statistics and after examining the log files, the runs seem fine and the calculations were done in the same amount of time as when we submitted one job per node.

Fig 1. ALTp for 2.6n gsim calculation with new scripts.

Jerry Gilfoyle's Enotebook page 259 - Change the bins for 2.6r (gpg)

[Modified Fri Sep 11 01:51:55 2009 (GMT) gpg]

Just to make switching back and forth between data sets I (belatedly) decided to have the same set of bins for 2.6n and 2.6r. I think I can get away with using the same values for the uncertainties since it only effects the last two bins which have large statistical uncertainties anyway.

Jerry Gilfoyle's Enotebook page 262 - Difference between fids and nofids (2.6r) (gpg)

[Modified Wed Sep 30 14:02:22 2009 (GMT) gpg 1

To see how different things are when I turn on the efids and pfids, I want to figure out the difference between ALTp with fids on and off (easy) with the proper uncertainties (not so easy). I can't just take the difference between the two extractions of ALTp and sum the uncertainties in quadrature because the data sets are not independent. The ALTp with no fids has many (about half) of the same data points the ALTp with fids has. I have to recast the problem in terms of independent measures of ALTp. In other words break each histogram like `hp_m_unwghtplus4` into the sum of two histograms; one with efids and pfids on and another for events that are excluded (i.e. at least one of the efid+pfid cuts fails).

To get started create all the appropriate histograms with uncertainties added in quadrature. Then get ALTp with fids off and compare it in fig 1 with ALTp derived by adding ALTp(efids+pfids) with ALTp(no efid OR no pfid). It works!

Fig 1. Comparison of ALTp(nofids) (black) with ALTp(efid+pfid) + ALTp(no efid OR no pfid) (red). This is only a partial statistics for for the 2.6r data set.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Calculate the difference between ALTp(fids on) and ALTp(fids off). Do NOT use the uncertainties calculated from ROOT. Get them by hand by treating ALTp(fids off) as the sum of ALTp(fids on) + ALTp(outside fids). The results is shown below for a partial analysis of the 2.6r data. All the points are consistent with zero within the error bars though there appears to be a bias toward negative results (fids on is a bit larger than fids off). The linear fit shown gives a slope that is just a wee bit more (in magnitude) than its uncertainty. I proclaim ALTp(fids off) = ALTp(fids on) for the 2.6r data!!!!

Fig 2. Plot of $\delta A_{LT}' = ALTp(\text{fids off}) - ALTp(\text{fids on})$ for 2.6r.

Jerry Gilfoyle's Enotebook page 264 - Checking effect of MM2 cut and fids and nofids on 2.6n (gpg)

[Modified Fri Oct 2 17:14:12 2009 (GMT) gpg]

First check the default ALTp. The results in figs 1-2 include the correction to the electron fiducial cut function discussed in figs 3-4 below.

Fig 1. Comparison of effect of different MM2 ranges. Fids off. I suspect the labels are backwards so the red points are MM2=0.83-0.91 GeV2.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Click [here](#) to view the object (Archive of root analysis code for 09-sep-30) you uploaded.

Fig 2. MM2 distribution for 2.6n with fit. Note the peak is at MM2 = 0.88 GeV2 as expected.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Q2 distribution comparison is shown in fig 3. What is the spike at low Q2 in the fids-on distribution? I saw this a long time ago and thought it was fixed. See

entry [37](#) and [40](#). Damn! More stuff to do.

2009-09-30 10:14:22

Fig 3. Comparison of electron singles Q^2 distribution with fids off and on.

There was a line in the electron fiducal cut function that was commented out that I put back in and it fixed the problem.

2009-09-30 12:14:43

Fig 3. Q^2 distribution with corrected electron fiducal cut function.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Now check the effect of turning on the efids and pfids. This effect is to magnify the dip and the default value is only about -0.05 instead of -0.07 which I expected from previous results. HMMMMM???

2009-09-30 22:16:25

Fig 4. Comparison of ALTp at 2.6n with fids off (black) and on (red).

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Fig 5. hp_m_unwghtplus4,5,6 hists. 4=5+6 Opps! I thought it was 5=4+6???

The Opps in the caption was the problem. The agreement is now perfect.

$\delta A_{LT}'$

2009-09-30 22:54:02

Fig 6. Difference between ALTp with fids on and off and with proper uncertainties.

Click [here](#) to view the object (Root macro) you uploaded.

Check that MM2=0.83-0.91 gives the 'deep' dip in ALTp. It does!

2009-10-01 15:15:05

Fig 7. Comparison of ALTp with MM2=0.83-0.91 GeV2 and with fids off (black) and on (red).

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The MM2 is not symmetric about the peak. It would be nice if it was so play with this for a bit.

2009-10-01 15:25:47

Fig 8. MM2 distribution with fit over the range used for the MM2 cut.

Click [here](#) to view the object (ROOT macro) you uploaded.

Scan the MM2 peak to see what happens to ALTp.

2009-10-01 21:49:05

Fig 9. ALTp for different regions of MM2 for 2.6n.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Extending the MM2 cut from 0.83-0.91 to 0.83-0.93 can be justified because it makes the cut symmetric about the peak, its 25% wider than the 2.6r cut, but the 2.6n peak is about 10% anyway so this may compensate for that. The fit to this MM2 region is shown below.

2009-10-01 21:59:19

Fig 10. MM2 fit for same analysis as fig 9 with new ranges on the central MM2 fit.

Click [here](#) to view the object (ROOT macro) you uploaded.

Scan ALTp using the new value for the central MM2 cut range. See the next fig. Notice that for the region in MM2 above the central region (blue) that ALTp is now about two sigma away from zero, unlike the results for the other two MM2 ranges (red and black). This may be a hint that we are getting into a region (the 'dip') where high-lying states (the #Delta?) which are not required to be zero at pm=0 (I think) are starting to have an effect. Notice the magnitude of the dip is a bit smaller than with MM2=0.83-0.91 GeV2, but not too much.

2009-10-02 08:53:49

Fig 11. Comparison of ALTp at 2.6n for different MM2 ranges.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Now check the effect of turning the fids off. It looks like the effect is zero within the error bars.

Jerry Gilfoyle's Enotebook page 265 - gemc EC (gpg)

[Modified Wed Nov 11 17:22:26 2009 (GMT) gpg 1

Some initial explorations of gemc and the EC geometry.

Fig 1. Geant4 generalized trapezoid roughly where the first EC layer is located.

Create a wireframe box to hold the EC lead and scintillator layers. Put in the first scintillator and roughly position the mother box in the correct position by eye. Need to get the full geometry.

Fig 2. Wireframe EC mother volume with the first scintillator layer inside.

Fig 3. Position the EC mother volume in a different sector.

Now use the sector mother volume instead of the root one. The EC mother volume was positioned in the sector coordinate system meaning the following.

x = 0 so the midplane of the sector coincides with the midplane of the detector.
y = perpendicular distance from scintillator closest to the beam to the beam.
z = desired distance from CLAS12 target - 5.0m

The individual scintillators and lead sheets were then placed inside the mother volume with the following coordinated.

z - points outward from the target and perpendicular to the face. Origin is in the center of the volume.
y - coincides with the midplane of the ideal detector.
x - points to the left looking out from the target.

Fig 4 shows the wireframe EC mother volume (red lines) reproduced in each sector. The blue material is the scintillator.

Fig 4. CLAS12 with partially filled (layers 1-6) EC.

Zooming in on one of the ECs from the side shows layers 1-6 of scintillator and layers 2-6 of lead.

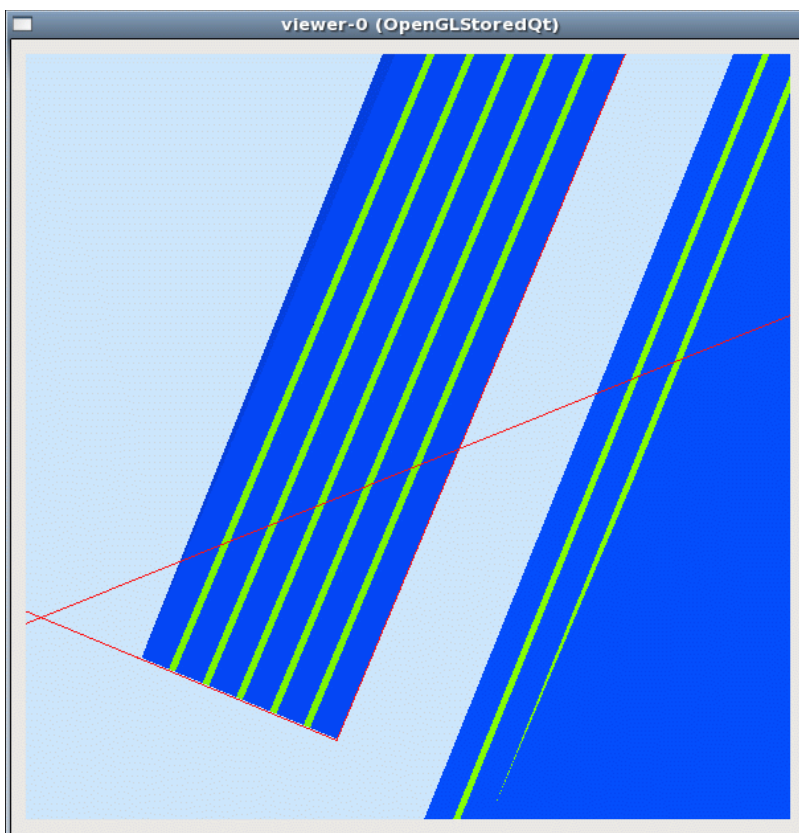

Fig 5. Side view of one of the EC boxes (red wireframe) showing scintillator layers 1-6 (blue) and lead layers 2-6 (green).

Click [here](#) to view the object (Perl script for generating GEANT4 volumes for Figs 4-5.) you uploaded.

Listing of the positions for the scintillator (left column) and the lead layers (right-hand column).

Put in all 39 layers of scintillator and 38 layers of lead. We still have to put in the projective geometry. Here I have assumed each layer is the same size.

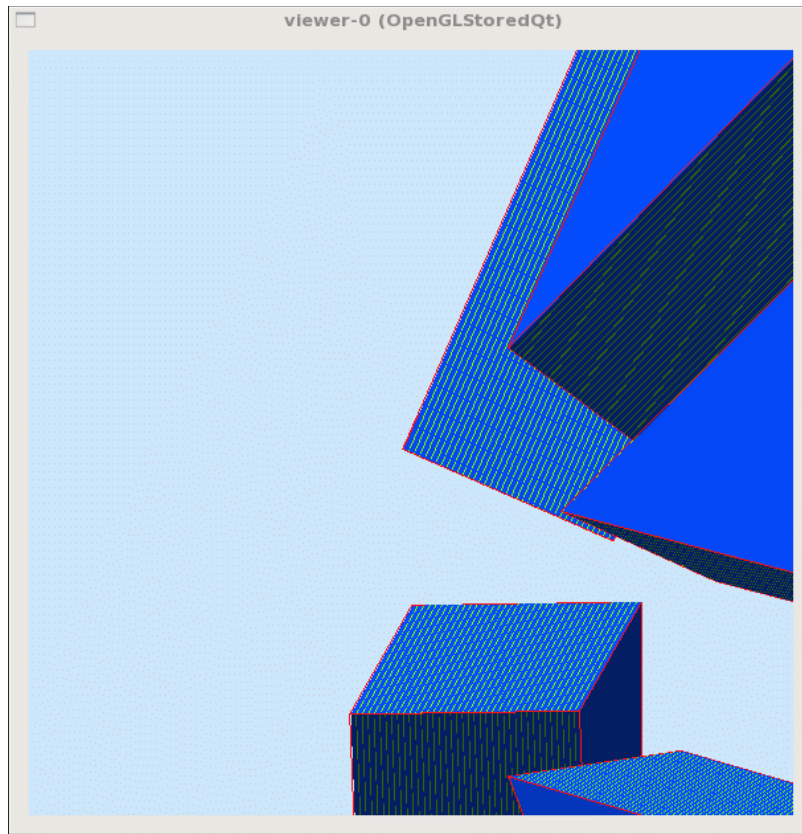

Fig 6. Nose of CLAS12 showing the layers of scintillator and lead in the EC.

Jerry Gilfoyle's Enotebook page 272 - GRRRR! Used wrong momentum corrections for 2.6n (gpg)

[Modified Fri Oct 9 13:54:45 2009 (GMT) gpg]

For the last set of analysis of the 2.6n data I had the momentum corrections for the 2.6r data. Redo it all! Well MM2, W, and fids stuff. Damn!!!!

Fig 1. W distribution for 2.6n with correct momentum corrections. It now looks like the appropriate W range should be 0.90-1.0 GeV instead of 0.90-0.99 GeV as I had.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Fig 2. MM2 distribution for 2.6n with prope momentum corrections. Distribution is a bit narrower so we may be able to shrink the range.

Redo with wider W cut first ($0.90 < W < 1.0$ GeV). It noticeably shrinks the size of the dip.

Fig 9. The MM2 distribution looks good for 2.6n and 0.89 < W < 0.99 GeV.

Click [here](#) to view the object (ROOT macro) you uploaded.

The width of the gaussian fit in fig 9 is about 0.04 GeV while I used a width of 0.10 GeV for the cut. Reduce the width of the cut to about 1 sigma and see what happens to the depth of the dip. It actually shrinks it a bit more, but we now have defensible widths and positions for the MM2 and W cuts.

2009-10-05 21:08:56

Jerry Gilfoyle's Enotebook page 274 - MM2 and W scans around the peaks for 2.6n (gpg)

[Modified Wed Oct 7 18:58:16 2009 (GMT) gpg]

Investigate the persistence of the dip in ALTP for 2.6n around the MM2 peak. The statistics for the region below the peak is so bad, we can't really say much. For the region about the peak, the dip is shallower and may be consistent within statistics with going away.

2009-10-06 21:28:04

Click [here](#) to view the object (ROOT macro) you uploaded.

The dip shrinks by 25% with the above W cut (the MM2 cut is the same as I had before). See entry 263. Use the same W cut as 2.6n ($0.89 < 0.99$ GeV). The entry 263 cut is $0.91 < 0.99$ GeV which looks too asymmetric to be defensible.

Jerry Gilfoyle's Enotebook page 277 - Variation of 2.6r ALTp dip and W cut (gpg)

[Modified Fri Oct 9 14:28:03 2009 (GMT) gpg]

We have studied the variation of the ALTp dip in the 2.6r data as we change the limits of the W cut for $0.83 < MM2 < 0.91$. The results are shown below. The left column is the bin number and W for the low-W limit; the next column is the bin number and W for the high-W limit; the right-hand column is the value of ALTp and its uncertainty in the fifth bin ($p_m 0.20-0.25$ GeV/c). See log-09-oct-09 for the Root commands and elog entry 276 (fig 6).

Jerry Gilfoyle's Enotebook page 278 - NDE differences for GMn (gpg)

[Modified Sat Oct 10 20:28:38 2009 (GMT) gpg]

Following up on John Schiffer questions during my ANL seminar, I have calculated the difference between the 2.6-GeV and 4.2-GeV EC NDE. See the plot below. There is a 1-2% difference between the two. This can be explained in the following way.

1. The efficiency curves are from two different beam energies.
2. So for a neutron of the same momentum p_n , it will strike different parts of CLAS for the two beam energies.
3. This difference is consistent with some of the super-pixel-to-super-pixel variation seen in the sector-by-sector efficiency measurements.

NDE(4.2 GeV) - NDE(2.6 GeV)

Jerry Gilfoyle's Enotebook page 279 - Effect of Mp cut on 2.6r (gpg)

[Modified Fri Oct 23 01:41:33 2009 (GMT) gpg]

I did not have the proton mass cut on in the previous analysis (dumb ass). This cut is needed to clean up the wings on the mass distribution that are presumably due to misidentified beam buckets. See entry 200.

Fig 1. Effect of turn on the m_p cut.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Fig 2. Add in a comparison with m_p cut on and fids on. It has a drastic effect on the uncertainties which grow by about a factor of 2.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now start working through the 2.6r cuts. Next plot is the same as Fig 2., but I notice the fids on results are a little different?? Not enough to worry about now. Wait, the cuts were not consistent for the different histograms. Rerun and replot for Figs after Fig 4.

2009-10-22 11:35:16

Jerry Gilfoyle's Enotebook page 281 - MM2 accuracy for 2.6n (gpg)

[Modified Mon Oct 26 02:17:49 2009 (GMT) gpg]

Check the accuracy of MM2 for the 2.6n data. The cuts on it are the following.

```
if (ep_event &&
    target_walls_ep &&
    //1 good_e_p_vertex &&
    good_electron_fiducial &&
    good_proton_fiducial &&
    //quasielastic_cut &&
    good_egiyan_threshold &&
    good_EC_pion_threshold &&
    good_electron_EC_fiducial &&
    good_electron_EC_trk_coords_fiducial &&
    good_mass_p &&
    good_EC_etot &&
    //good_sampling_fraction &&
    good_photoelectrons) {

  hw1b->Fill(w1);

  if (phi_p_deg < -30) {
    hphiMM2->Fill(mm2,phi_p_deg+360);
  } else {
    hphiMM2->Fill(mm2,phi_p_deg);
  }
}
```

Fig 1. phi_p versus MM² for 2.6n for e-p events.

Jerry Gilfoyle's Enotebook page 283 - MM2 Accuracy for 2.6r (gpg)

[Modified Tue Oct 27 19:47:02 2009 (GMT) gpg]

Now do the same thing we did on the 2.6n data in entry 281. First get the centroid of the angular distribution for the scattered electron. The Mathematica notebook used to get the correction factors is below.

Click [here](#) to view the object (Mathematica notebook for calculating MM2.) you uploaded.

2009-10-26 14:18:12

Fig 1. Angular distribution of scattered electron for 2.6r.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

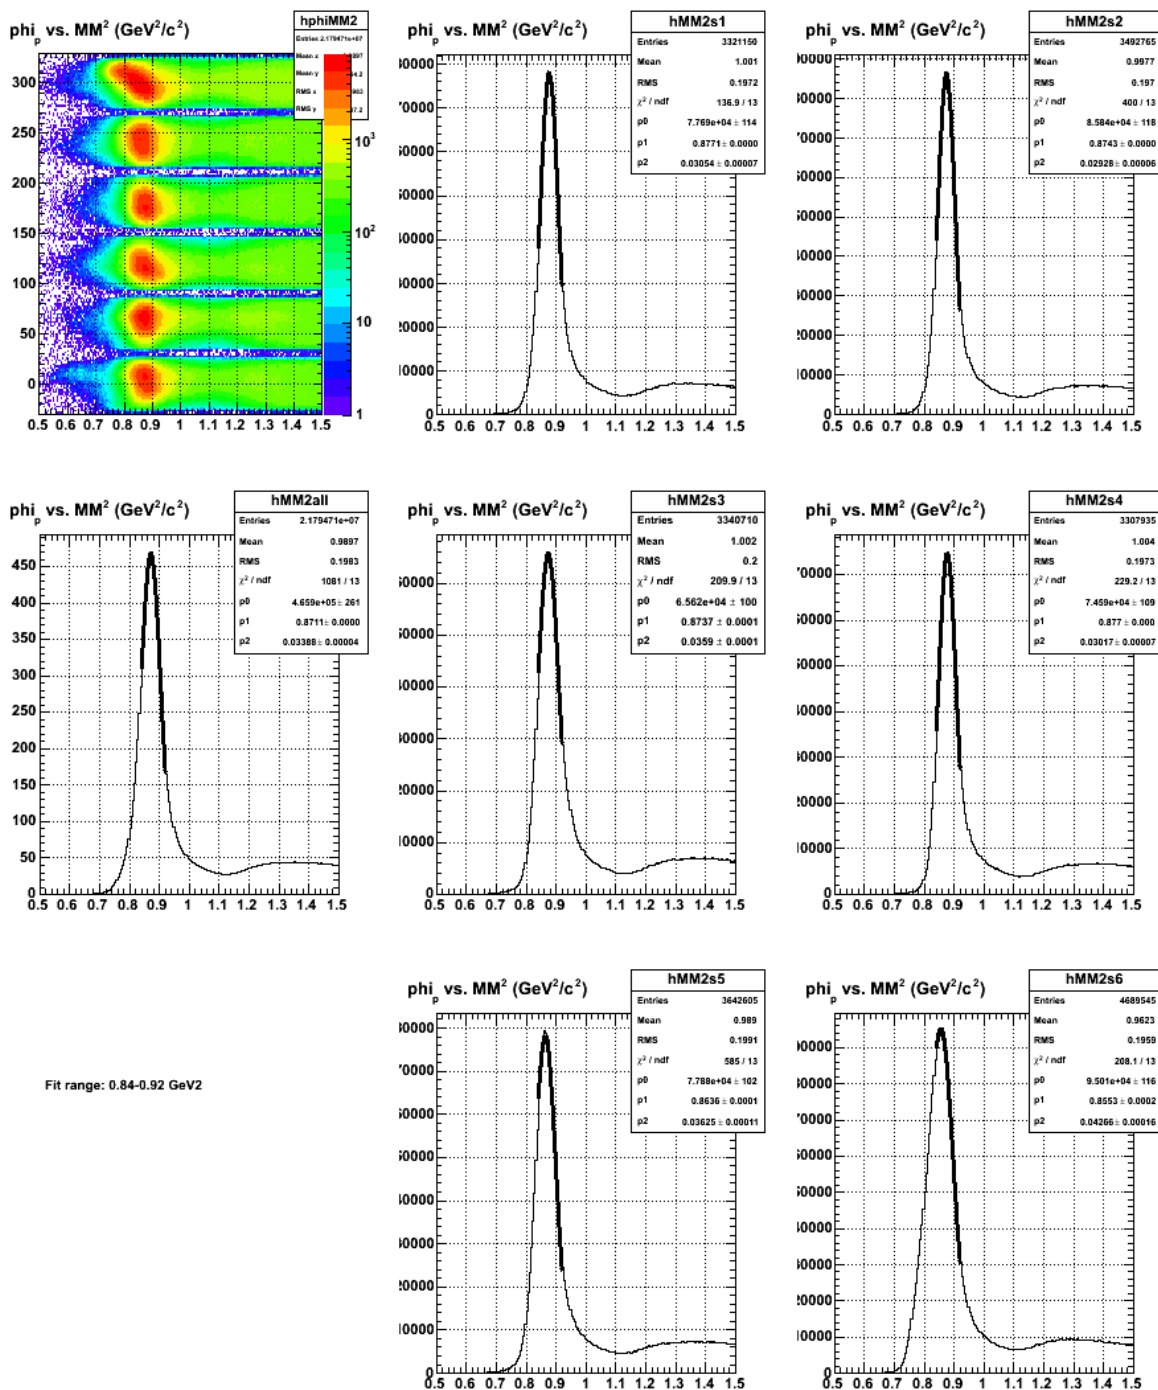

Fig 2. Comparison of 2.6n (note 2.6n) fit range and MM2 cut range for 2.6r results (which uses 8.83-0.92 GeV2 for the MM2 cut). This makes the disagreement with the data and the fit range look worse.

Click [here](#) to view the object (ROOT macro) you uploaded.

I applied the shift to the proton momentum to improve the agreement between the peak in the MM2 spectra and the expected neutron value of 0.88278 GeV2. Things look good for sectors 1-5. Sector 6 shows a dramatic (a factor of 4-5) drop in the number of events and the peak is still far from the expected value. A mystery??!!

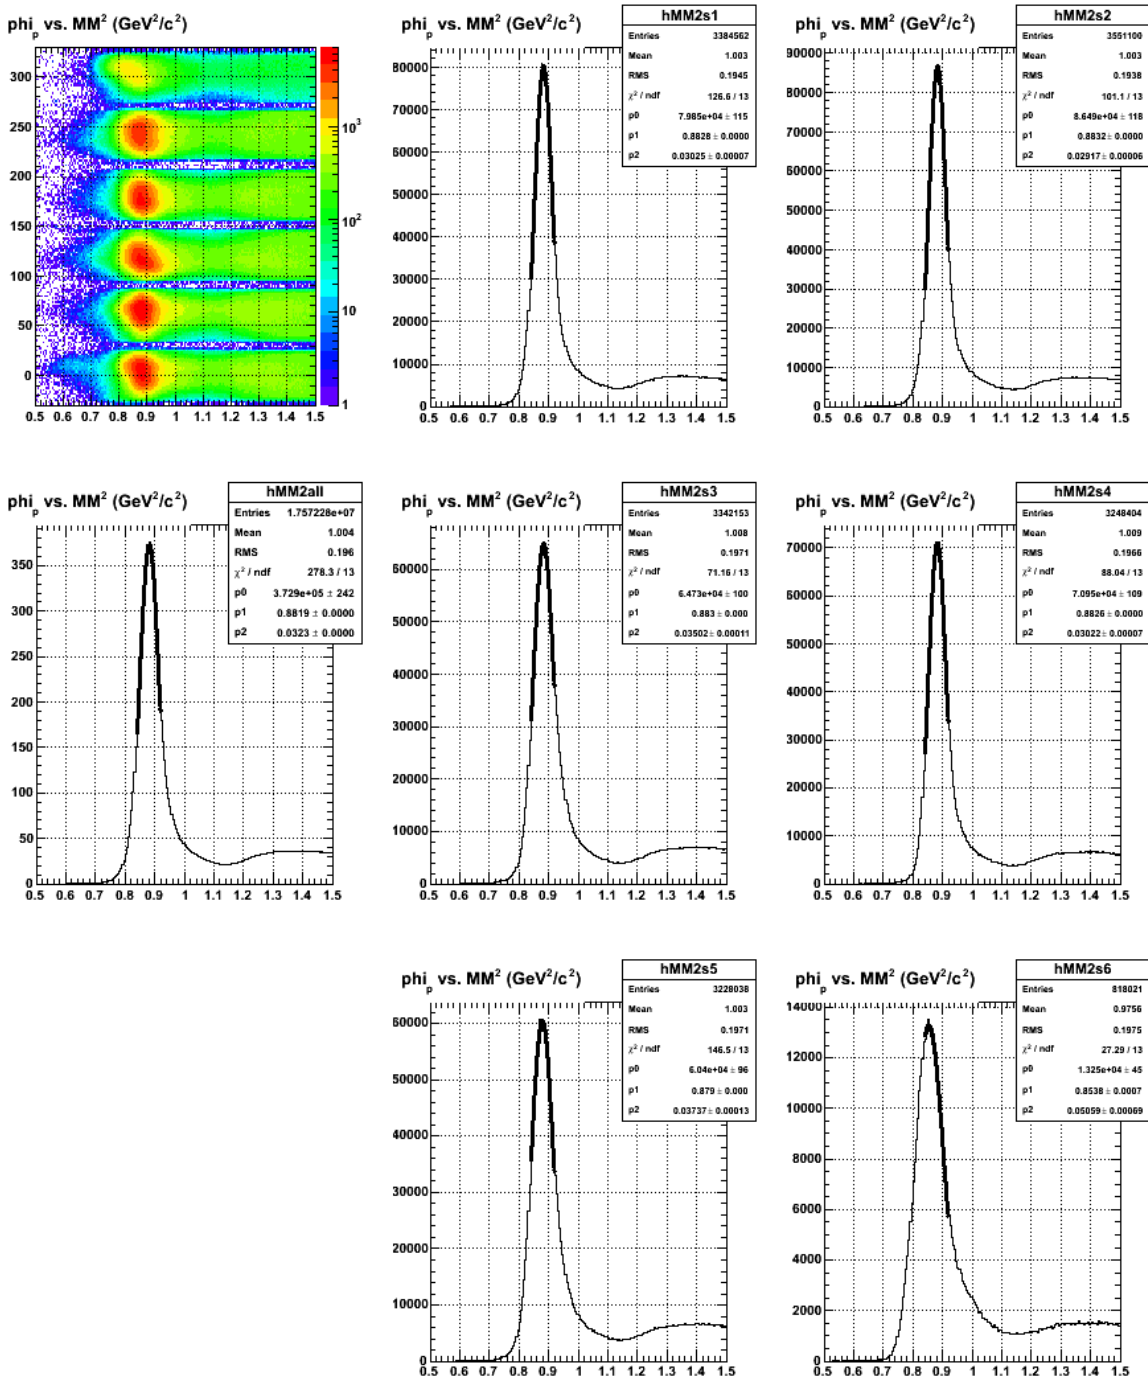

Fig 3. MM2 spectra sector-by-sector with proton momentum shifts in place. Note the weirdness of sector 6.

Click [here](#) to view the object (ROOT macro) you uploaded.

The sector 6 problem is due to the mass_p cut. For the first 100000 events in /clas_024381.a00.b00.root I get 105 sector 6 events with the mass_p cut on and 522! with it off!

2009-10-27 10:52:51

Fig 7a. Proton mass with p_p shift on.

2009-10-27 10:56:26

Fig 7b. Proton mass with p_p shift off.

Do not use the shifted proton momentum for the mass_p cut and things look ok. Hmm. The mass of the proton generated from tracking looks ok but is off for the MM2. When I fix the proton momentum so I get the correct MM2, the proton mass is off. Does this mean there is a problem with the proton angle measurement??

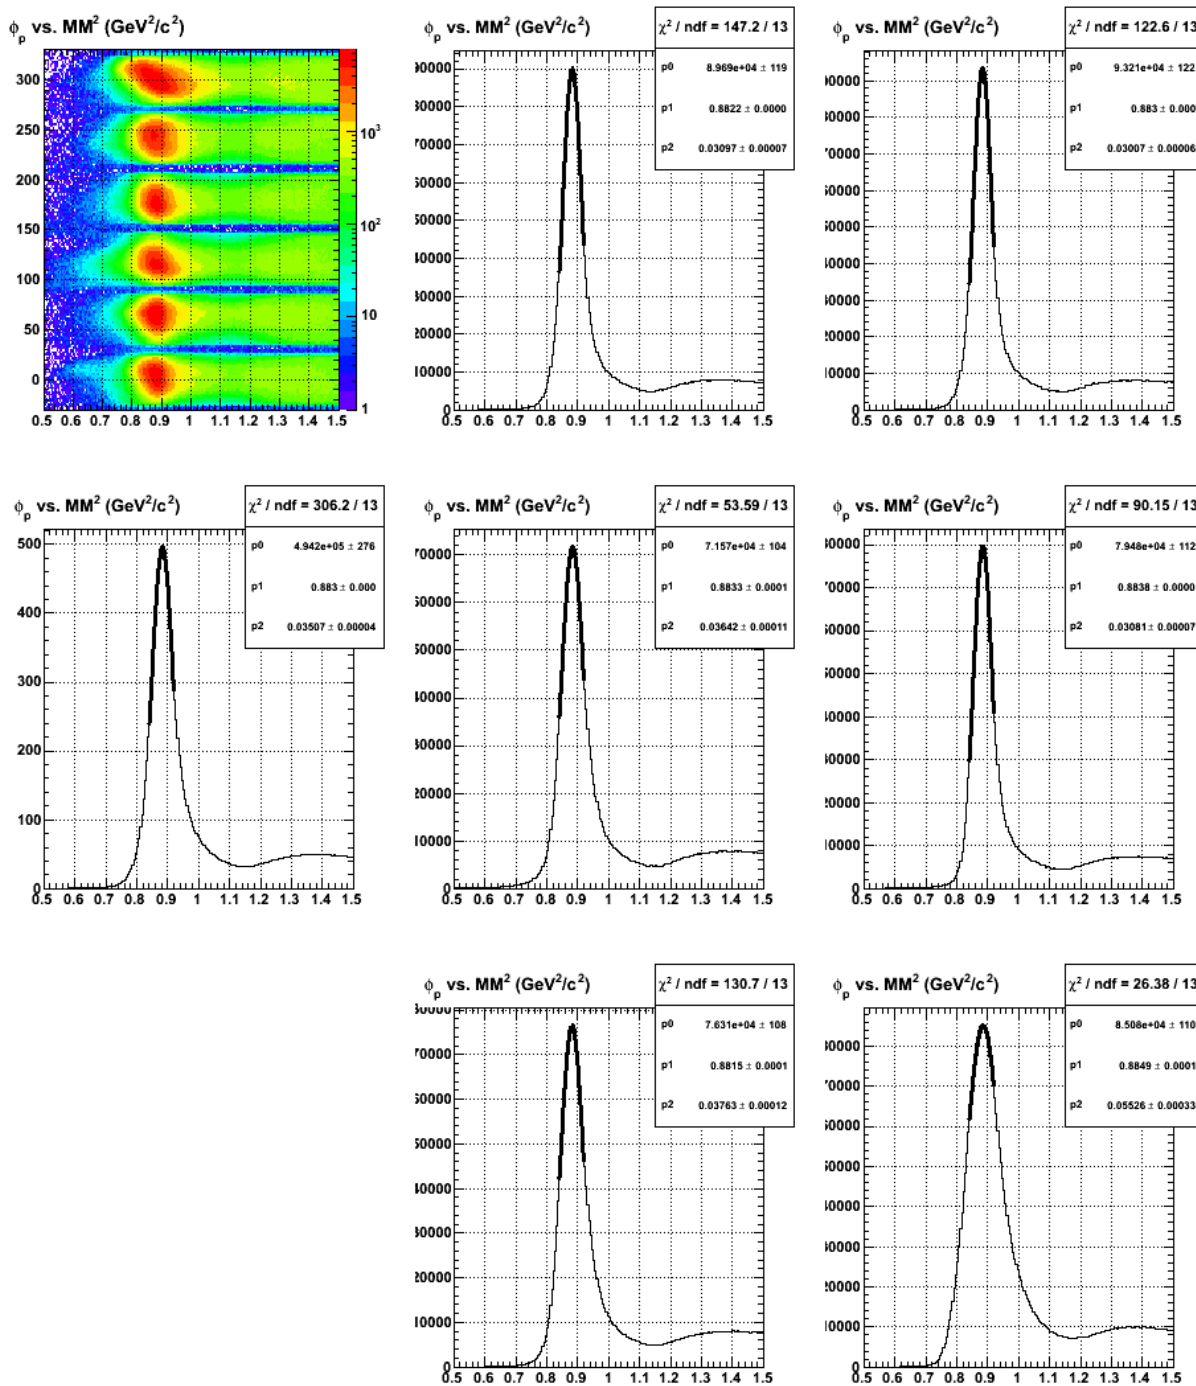

Fig 8. MM2 comparison sector-by-sector after turning off the proton momentum shift for the proton mass cut.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Jerry Gilfoyle's Enotebook page 284 - Effect of proton momentum correction on 2.6r (gpg)

[Modified Wed Nov 4 17:13:53 2009 (GMT) gpg]

After adding the scaling, fudge factor to the proton momentum to make the MM2 come out better we look at our old favorites to see if there are significant changes. The magnitude of ALTp at the dip decreased by about 8%.

2009-10-27 16:15:07

Fig 1. Comparison of 2.6r, ALTp with fids off (black) and on (red) after including the proton momentum shift to correct the MM2.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

2009-10-27 16:20:47

Fig 2. Difference between fids on and off for 2.6 ALTp after putting in proton momentum correction.

Do the W scan next. The low-W scan shows the dip disappearing, but for the hi-W region, the dip in ALTp has increased! This is likely due to the large width of the sector 6 data. Try excluding that from the scan.

2009-10-27 16:40:08

Fig 3. W scan of 2.6r with proton momentum correction in.

2009-10-27 17:04:36

Fig 4. Increase the width of the W cut by 60% to see if we can see the bigger dip seen in Fig 3. It doesn't appear??

Click [here](#) to view the object () you uploaded.

When I slide the cut up in W, the big broad dip appears!

Fig 5. Scan of the W cut to reveal a large, broad dip on the high-W side of the neutron peak!!!

Jerry Gilfoyle's Enotebook page 285 - test (Jerry Gilfoyle)

[Modified Wed Nov 4 16:14:02 2009 (GMT) Jerry Gilfoyle]

test

test again.

Jerry Gilfoyle's Enotebook page 286 - Recovering Back to the 2.6r Future (gpg)

[Modified Mon Nov 23 14:45:50 2009 (GMT) gpg]

I had a long page dealing with the broad, deep, dip at the high-W side of the 2.6r dip that has magically appeared when I scan at higher W. That page was lost when I hit a quota limit on the DOE2000 elog. The broad, deep dip was not seen before. Actually it was. See entry 88, Fig 11, top panel. I wasn't careful enough. See also entries 57, 117, 118, 119.

Below shows the W spectrum for 2.6r and the new W scan with a wider W cut to define QE events. The script subbins.C was used to generate Fig 1b from the TH3D histograms of p_m vs. W vs. MM2. I believe, but I'm not absolutely sure the next figure excluded sector 6.

2009-11-04 10:20:07

Fig 1a. W spectrum for 2.6r showing new W cut.

2009-10-30 09:45:22

Fig 5. Latest version of 2.6r ALTP.

Click [here](#) to view the object (ROOT macro) you uploaded.

The stuff below this line EXCLUDED sector 6. Sector 6 has a much broader MM2 distribution than the other sectors of CLAS.

My latest thought is to keep the W range narrow (0.89-0.99 GeV) and show ALTP clearly in the dip region (W=1.04-1.14 GeV) and in the low-W region. See next plot which I know for sure excludes sector 6.

2009-11-04 21:19:55

Fig 6a. W scan for 2.6r. The high-W scan is centered on the dip (no sector 6).

2009-11-04 21:28:04

Fig 6b. W distribution for 2.6r with W cut marked in red (no sector 6).

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

The plot below compares ALTP vs. p_m for 2.6r and different W ranges. The black squares are the default ALTP with $0.89 < W < 0.99$ GeV. Moving just outside this region (red, open squares) there is a new dip at $p_m = 0.3$ GeV/c for $0.99 < W < 1.04$ GeV. Notice also the lowest p_m bin. There are very few counts in this bin (huge uncertainty) which is indicative of inelastic processes. I have seen this in the past when I looked at ALTP in the dip region. This points to the possibility that the origin of the new dip is an inelastic process and not associated with the quasielastic peak. Continuing higher in W, the next region (blue, open circles and $1.04 < W < 1.09$ GeV) shows the same behavior; large dip at $p_m = 0.3$ GeV/c and no counts near $p_m = 0$ GeV/c. There is a big change in the next region (green, solid squares and $1.09 < W < 1.14$ GeV). The large dip disappears! Perhaps this is evidence of an interference between a large, quasielastic amplitude and a small, inelastic one. The large QE amplitude amplifies the small inelastic region where the QE amplitude is large and the effect disappears as we

move out of the QE region.

2009-11-05 10:50:56
Fig 7. Comparison of 2.6r ALTP for different W ranges showing the rapid change approaching the dip region.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT macro subbins.c used to generate variable bin ALTP from TH3D histograms.) you uploaded.

The last plot shows what happens for $1.14 < W < 1.19$ GeV. Basically there are no counts and ALTP is consistent with zero over the full p_m range.

2009-11-05 11:05:57

Jerry Gilfoyle's Enotebook page 288 - Effect of fiducial cuts on 2.6r W spectrum (gpg)

[Modified Mon Nov 9 03:16:04 2009 (GMT) gpg]

The plots below is a somewhat random observation of the effect of fiducial cuts on the 2.6r data. The left-hand panel shows the W spectrum with the electron and proton fiducial cuts turned on. The right-hand panel shows the same thing with those cuts turned off. There are, not surprisingly, many more events in the left-hand plot, but the shape is also different. the proportion of QE to inelastic events is much larger with the fiducial cuts off. This is likely due to the lower limit on the Q2 distribution for the no-fiducial-cut results. Lower Q2 usually means more QE events and a smaller fraction of inelastic events.

Fig 1. Comparison of W spectra with fiducial cuts on (left panel) and off (right panel) for 2.6r.

Jerry Gilfoyle's Enotebook page 292 - Dependence of ALTp on MM2 for 2.6r (gpg)

[Modified Sat Nov 28 00:58:58 2009 (GMT) gpg]

A last (!) study of the dependence of ALTp on the MM2 cut. Use the optimum W cut ($0.89 < W < 0.99$ GeV). The conclusion here is that for the optimum W cut, ALTp drops off rapidly as we move above or below the neutron peak in the MM2 distribution. The first plot shows a comparison of the default ALTp with a different MM2 range to agree with fig 5 in entry 119.

2009-11-23 10:33:19

Fig 1. Comparison of the default ALTp with a variation in the MM2 cut. See below for a revised figure.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The results in the l.h.s. of fig 1 are consistent with entry 119, but seem to be at odds with my results studies of ALTp. However, the rogue dip is seen when I vary W NOT MM2. Plots below show the MM2 distribution with the QE cut on and off. The difference between the two plots with no QE cut is due to the different bin size (the hMM2total histogram has bins that are twice as large as the hW1b histogram so each bin has about half the number of counts) and hW1b has no proton mass cut that narrows the proton definition and reduces the inelastic tail at high MM2..

2009-11-23 11:57:28

Move the MM2 cut a bit higher to avoid overlapping the default MM2 range for 2.6r. The MM2 range for the green points is 0.91-0.99 GeV.

Click [here](#) to view the object (ROOT macro) you uploaded.

2009-11-23 11:38:00

Fig 2. MM2 distributions. QE cut is $0.89 < W < 0.99$ GeV.

Click [here](#) to view the object (ROOT macro) you uploaded.

Dumb Ass!! I put the W plot in the upper right-hand panel instead of the MM2 for comparison. Show the appropriate MM2 plot below.

2009-11-23 12:39:46

MM2 dependence for 2.6r.

Click [here](#) to view the object (ROOT macro) you uploaded.
Do the plot for the MM2 region below the neutron peak.

2009-11-23 12:44:19

MM2 distribution from #phi vs. MM2 distribution.

2009-11-23 12:04:37

Fig 3. Comparison of the default ALTp with a variation in the MM2 cut at low neutron mass. The MM2 range is 0.75-0.83 GeV2 NOT 0.75-0.91 GeV2.

Click [here](#) to view the object (ROOT macro) you uploaded.

2009-11-25 00:16:15

Fig 4. Comparison of 2.6r ALTp with a revised high-MM2 range to be consistent with other plots and the CAN. The missing, sixth point is 0.061 ± 0.029

Click [here](#) to view the object (Root macro) you uploaded.

2009-11-25 00:11:32

Fig 5. Comparison of 2.6r ALTp with revised low-MM2 range. The upper limit on the default ALTp is 0.91 GeV/c NOT 0.99 GeV.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 293 - Dependence of ALTp on W for 2.6r (gpg)

[Modified Wed Nov 25 05:00:04 2009 (GMT) gpg]

Now fix the MM2 cut at $0.83 < MM^2 < 0.91 \text{ GeV}^2$ and vary the W cut. This is where I should see the rogue dip.

2009-11-23 12:26:59

Fig 1. Comparison of ALTp for the default QE cut and for high W for 2.6r. First bin is 0.893786 ± 0.698912 which does not show up on the plot.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

The rogue dip.

2009-11-23 12:22:12

Fig 2. Comparison of ALTp for the default neutron cut on MM2 and 2.6r. Revised version is below.

Click [here](#) to view the object (ROOT macro) you uploaded.

2009-11-23 13:05:57

Fig 3. Comparison of ALTp for default (black) and for the W range just above the QE cut showing the rogue dip.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now add plots of W spectra to illustrate cut ranges. The difference in scales can be explained because the l.h.s of fig 4 has half the bin width in GeV and does not have the extra proton mass cut applied to clean up the mass of the proton.

Fig 4. Comparison of W spectra projected out of 3D histogram and from 1D histogram in eod5.C.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 294 - Dependence of ALTp on MM2 for 2.6n (gpg)

[Modified Sat Nov 28 00:47:11 2009 (GMT) gpg]

Now do a study of the MM2 dependence of ALTp for 2.6n so the scans are consistent with the 2.6r results in the previous entries. There are small differences between ALTp and previous results. I ran this with the MM2 momentum corrections turned off so I am rerunning the analysis with those corrections turned on to see if there is any difference. This difference is a bit perplexing. Turning off the MM2 momentum corrections and things look almost exactly as they did before. See below for revised plots.

2009-11-24 11:44:26

Fig 1. Comparison of 2.6n ALTp with optimum MM2 and MM2 above the neutron peak.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

2009-11-24 11:58:54

Fig 2. Revised the range of the upper MM2 scan. Opps! The true range for the red points is 0.92-1.1 GeV2

Fig 4. Revised comparison of 2.6n ALTp with high-MM2 region (red). The default MM2 region is really 0.84-0.92 GeV2 and the high-MM2 region is 0.92-1.1 GeV2 NOT what is labelled on the plot.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

2009-11-25 00:33:02

Fig 5. Revised comparison of 2.6n ALTp with low-MM2 region. The missing fifth point is -0.12 +/- 0.06.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 295 - Dependence of ALTp on W for 2.6n (gpg)

[Modified Wed Nov 25 04:41:02 2009 (GMT) gpg]

Now do the W scan for 2.6n.

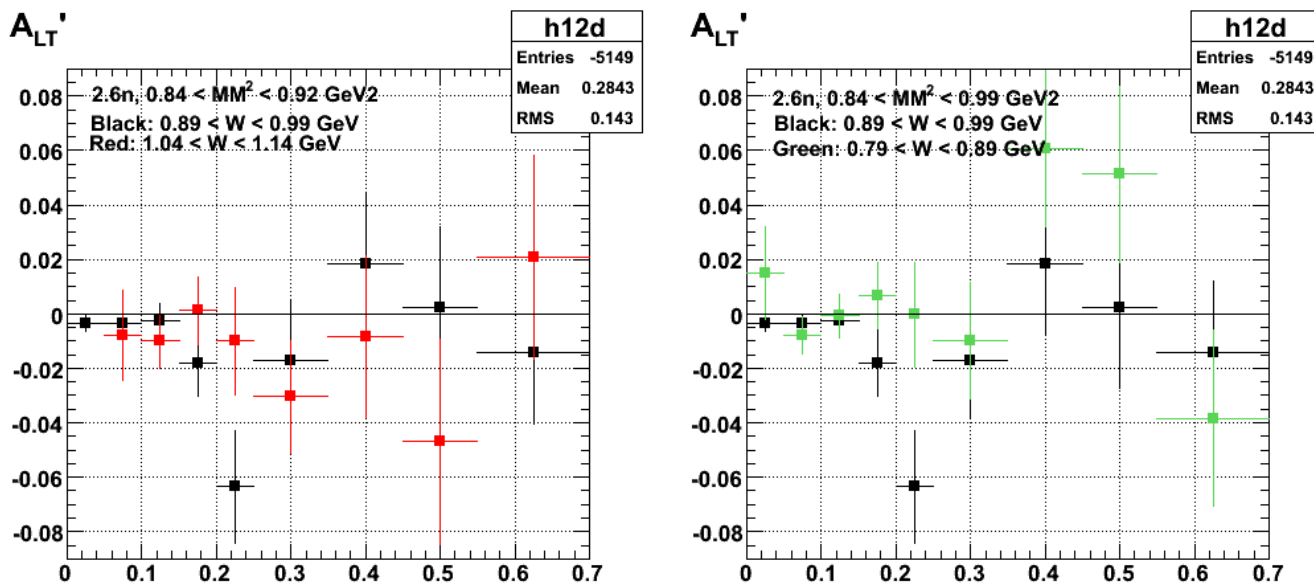

Fig 1. Scans of W for 2.6n above and below the QE peak. The lowest red, p_m on the lhs is off scale and is 0.2 +/- 0.2.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Fig 2. W spectra with neutron MM2 cut off (left) and on (right).

Click [here](#) to view the object (ROOT macro) you uploaded.

Recall the problem from the previous entry that ALTp looks a little different. I suspect the effect of the MM2 momentum correction. Re-analyze the data and it looks closer to the previous results especially at small p_m. See entry 282. Results are below. The W spectra above are still usable in the CAN.

2009-11-24 18:47:46

Fig 4. Comparison of 2.6n ALTp with optimum MM2 and MM2 above the neutron peak. The lowest pm point is 0.5 +/- 0.2 which is suspicious and justifies excluding these data from ALTp for QE kinematics.

Table 3: Rates and statistical uncertainties for quasielastic scattering.

Fig 2. Run statistics in CLAS12 GMn proposal.

The next plot shows a comparison of the Kelly fits before and after adding the CLAS6 GMn data (like fig 1) and the Kelly fit to the GMp data. This comparison was motivated by the comment in the Albreico paper that adding the CLAS6 GMn data to the world's data made the GMn fit look more like GMp. It certainly does not look like that here??!!

Fig 3. Comparison of GMn fits and Kelly GMp results.

Throw out the first four points in Fig 7 because there is no neutron acceptance in that range.

Fig 8. Same as Fig 7 with low- Q^2 points removed because of acceptance/detection efficiency effects.

Jerry Gilfoyle's Enotebook page 297 - GEn/GMn (gpg)**[Modified Tue Dec 1 14:24:29 2009 (GMT) gpg]**Study of GEn/GMn for update. The first plot shows the ratio $\mu_n G_E^n / G_M^n$ assuming the dipole for GMn and Galster for GEn.**Fig 1. GEn/GMn plot.**Click [here](#) to view the object (Mathematica notebook) you uploaded.

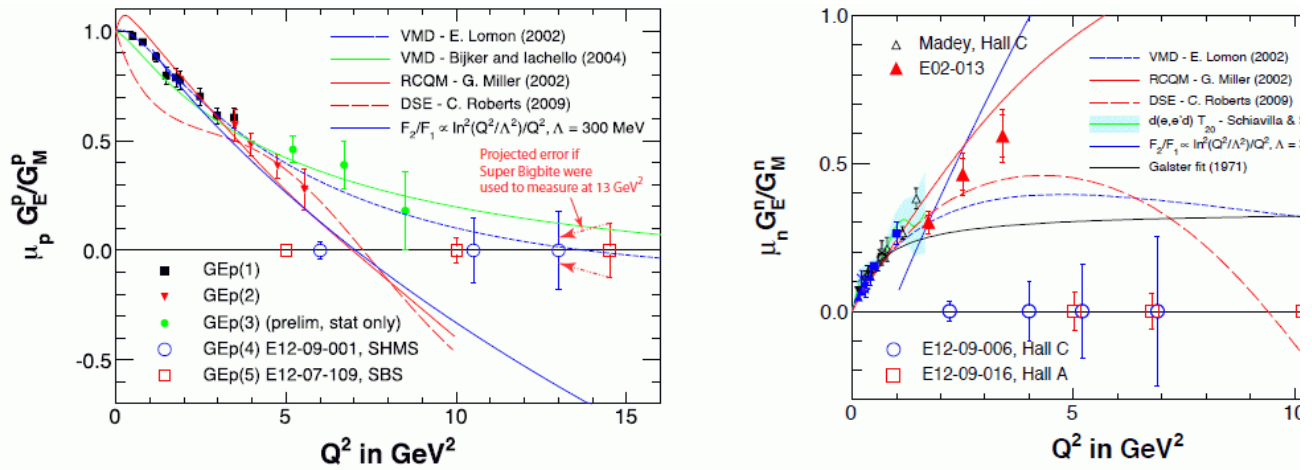

Fig. 1. Shown are existing data and projected errors for measurements of the ratios of the ratios of the proton (left panel) and neutron (right panel). The errors for the measurements made within the Super Bigbite project are shown by the squares. On the left panel are shown the published results of GEp(1)¹, GEp(2)⁸, preliminary results from GEp(3)⁹, the proposed points of GEp(4) with SHMS in a 90-day run¹⁰ and projected results of GEp(5) in a 60-day run¹¹. To emphasize the larger statistical power of ten) of GEp(5), we indicate on the figure the size of the error bars that would be using SBS to run at 13 GeV^2 . On the right-hand panel, for G_n^n / G_M^n , we show published results including those due to Madey and coworkers¹², and preliminary results of GEn(1) (E02-013) and GEn(2) (E12-09-006) with SHMS (open blue points). We also show the projected errors of GEn(2)¹⁴, which is part of the Super Bigbite project E12-09-006¹⁵ with SHMS (open red squares). Note that at roughly 7 GeV^2 , the highest Q^2 reached by the SHMS experiment, GEn(2) achieves an error four times smaller, and with one quarter the running time. This illustrates the $\times 50$ advantage in Figure-of-Merit of GEn(2) over the GEn(1) experiment.

Below is a tarred, zipped file containing histograms of the inelastics for Q2=12-14 GeV2 which show a factor of five drop in the number of IN events when the hermiticity cut is turned on. I ran this with way too many QE events so I am going to rerun the simulations with just QE events to speed things up.

Click [here](#) to view the object (gzipped tar archive of good IN hists.) you uploaded.

Fig 5. Progression of cuts to select QE events. Used submit_gmnsim.pl 700 50000 1, theta_pq < 1.5 deg.

major oopsss!! geneV was halting prematurely when it encountered a particle that was unknown to it. these turned out to be kaons (K+,K-,Kshort,Klong). i added the code to handle these and reran it.

Jerry Gilfoyle's Enotebook page 300 - Effect of changing exit channels in genevD (gpg)

[Modified Thu Dec 17 02:49:24 2009 (GMT) gpg]

Just cause I have nothing better to do and no deadlines are breathing down my neck, I decided to look at the effect of changing the composition of the decay channels chosen in genevD and set in genev_template.inp. I tried turning everything on and rediscovered what I dimly remember from two years ago. The first plot shows the standard set.

Fig 1. Progression of cuts on the neutrons with the standard genevD input. Done with the parameters below.

```
submit_gmnsim.pl 1000 23000 1
```

```
15 ! number of activated channels
1,2,5,6,7,11,12,15,16,19,21,22,27,28,29 ! channels ID (in one line, ID separated by a comma.g 1,3,4 ...)
```

2009-12-10 21:00:28

Fig 2. Turn everybody except the strangeness-producing decay channels cause they screw things up (see elog 09-dec-16).

```
submit_gmsim.pl 1000 23000 1
```

```
27          ! number of activated channels
1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,27,28,29      ! channels ID (in one line, ID separated by a comma.g 1,3,4 ...)
```

The conclusions seems to be as before. The inelastic cross section in the standard set rises more rapidly with W2 than when I turn all the channels on (except the strangeness-producing ones). With the everybody-on settings I do get more inelastic events which may be because the multiplicity is higher so the number of events that gets through FastMC12 is larger. Go back to the standard set.

Jerry Gilfoyle's Enotebook page 301 - Progression of cuts plot for update (gpg)

[Modified Sun Jan 3 03:03:08 2010 (GMT) gpg]

After the problem with the strangeness-producing channels in genevD, I redo the progression of cuts plots for the update. The first pair of plots is a test run before I do a real long run to get good statistics. Look to the bottom of this entry for the final results.

2009-12-10 14:18:00

My choice for the QE/IN ratio does not reproduce the fraction of inelastic events with $W_2 < 1.2$ GeV² (0.12) that I used in the draft of the update. To be consistent with that result I increased the proportion of inelastic events. See below.

2009-12-31 15:09:00

The Hall A GMn proposal will claim to use a very restrictive theta_pq cut to isolate the QE events. Some of their W2 spectra with theta_pq < 0.5 deg show this could work so I want to see how we can reduce the inelastic background by reducing the theta_pq cut relative to the examples above in Figs 7-8. First redo the analysis of Figs 7-8 requiring theta_pq < 1.0 deg.

Jerry Gilfoyle's Enotebook page 302 - Testing Hermiticity cut on 4.2-GeV, E5 data (gpg)

[Modified Thu Dec 24 19:11:51 2009 (GMT) gpg]

Kawtar suggested looking at the E5 data to test the effect of the hermiticity cut.

2009-12-18 10:46:24

Fig 1. Left panel: effect of theta_pq and hermiticity cuts alone.

Turn off efids and pfids and things look more Jlish. In the left-hand panel there is a big drop in the QE pick when I turn on the hermiticity cut. I don't understand this. In the simulations there is no effect on the QE pick which makes sense. this does not!!!!???????????????????????????? Yes it is! See below.

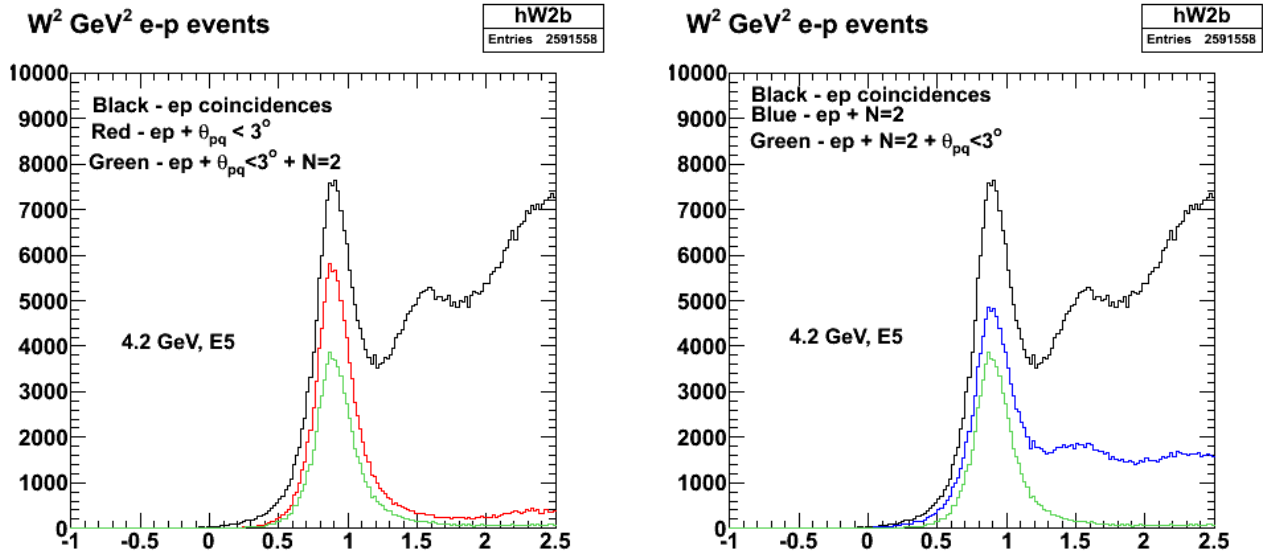

Fig 4. Comparison of various cuts on the W2 spectra for the 4.2-GeV data. Fiducial cuts for electrons and protons are turned off.

Click [here](#) to view the object (ROOT macro) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

Yeehaa! The plot below shows the W2 spectrum for several sets of combinations and cuts. The big point is that when I add together the histograms for theta_pq+hermiticity (green) with epn (gray) cuts, the QE peak matches the theta_pq only spectrum (red), but is noticeably less for the inelastic region. The number of counts is still smaller than JL.

Fig 4. Comparison of various cuts for the W2 spectra for the 4.2-GeV data. Fiducial cuts and other cuts are off to reproduce the number of counts.

Jerry Gilfoyle's Enotebook page 303 - 4.2-GeV analysis in preparation for update presentation (gpg)

[Modified Sun Dec 27 00:45:40 2009 (GMT) gpg]

In order to prepare for the PAC update talk Kawtar suggested that I look at the effect of the hermiticity cut on the E5 data. The θ_{pq} cut removes most of the inelastic events from the W2 spectrum, but we could still study the impact of the hermiticity cut by turning off the θ_{pq} cut. With that in mind, I first decided to look at what happens when I add the hermiticity cut to the θ_{pq} cut. Below are the results of a recent analysis of the 4.2-GeV, E5 data. The left-hand panel in Fig 1 shows the effect first of the θ_{pq} cut (red histogram) followed by the addition of the hermiticity cut (veto events with $N > 2$ where N is the number of tracks). The surprise here is that the hermiticity cut removes about half of the quasielastic (QE) events. In the right-hand panel modifying the hermiticity cut from $N > 2$ to $N > 3$ restores most of the lost QE events.

Fig 1. The left-hand panel shows the effect of the θ_{pq} cut on the W2 distribution for epX events (red) followed by adding the hermiticity cut (no $N > 2$ tracks). The right-hand panel shows the W2 distribution if the hermiticity cut is changed to a veto of events with the number of tracks $N > 3$ (blue).

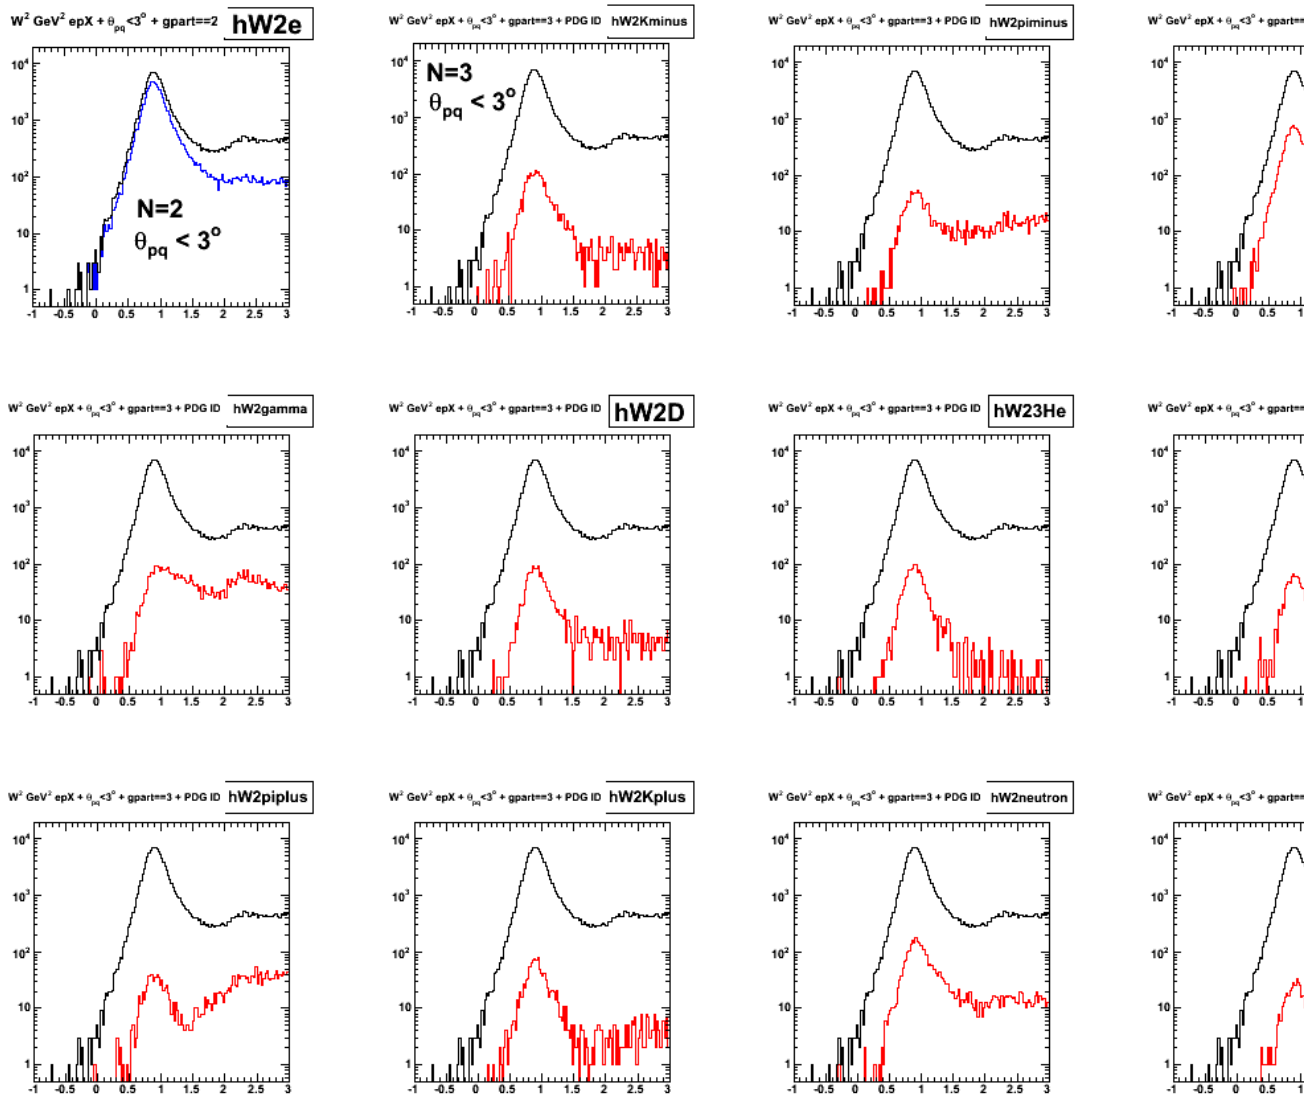

To understand the source of these apparent $N > 2$, QE events consider the next plot. It shows the value of the particle ID excluding the electron and proton. The numbers use the PDG convention for meaning except the ones in the 40's which use a geant convention. The most prominent species the $id=0$ one which means the particle was not identified though this likely a real track. There is also a large number of photons (from radiative events perhaps) and neutrons (real epn events!).

2009-12-24 14:10:36

Fig 2. Distribution of PDG ID numbers for N>2 events excluding the electron and proton.

Taking this further I show the next figure which is the W2 distribution for all the different particles seen in Fig 2. The most prominent one is the one with id=0 (unidentified tracks) which makes up most of the missing events (peak at about 800 events). Nevertheless, there are seven other channels (K-,K+,neutron, proton, D, 3He, 4He) that show a significant QE peak and low inelastic background with a peak of about 100 events or less). Coincidences with things like K+ are presumably random coincidences. This 'large' of random events is surprising to me,

2009-12-25 23:03:02

Fig 3. W2 distribution for N=3 events and broken down by particle species. The black histogram in each case is W2 distribution for epX events with just the θ_{pq} cut. The upper, left-hand panel shows the results for epX events with the θ_{pq} and the N=2 cut. All the other panels show W2 for N=3, epX events with the labelled particle and the θ_{pq} cut.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Add the histograms for the 'good' random channels excluding the id=0 histogram and you get about the same number of events. See fig. below.

2009-12-25 23:13:34

Fig 4. Comparison of W2 distributions for N=3, id=0 events (red) with the sum of histograms for channels (K-,K+,neutron, proton, D, 3He, 4He) and N=3.

Click [here](#) to view the object (Root macro) you uploaded.

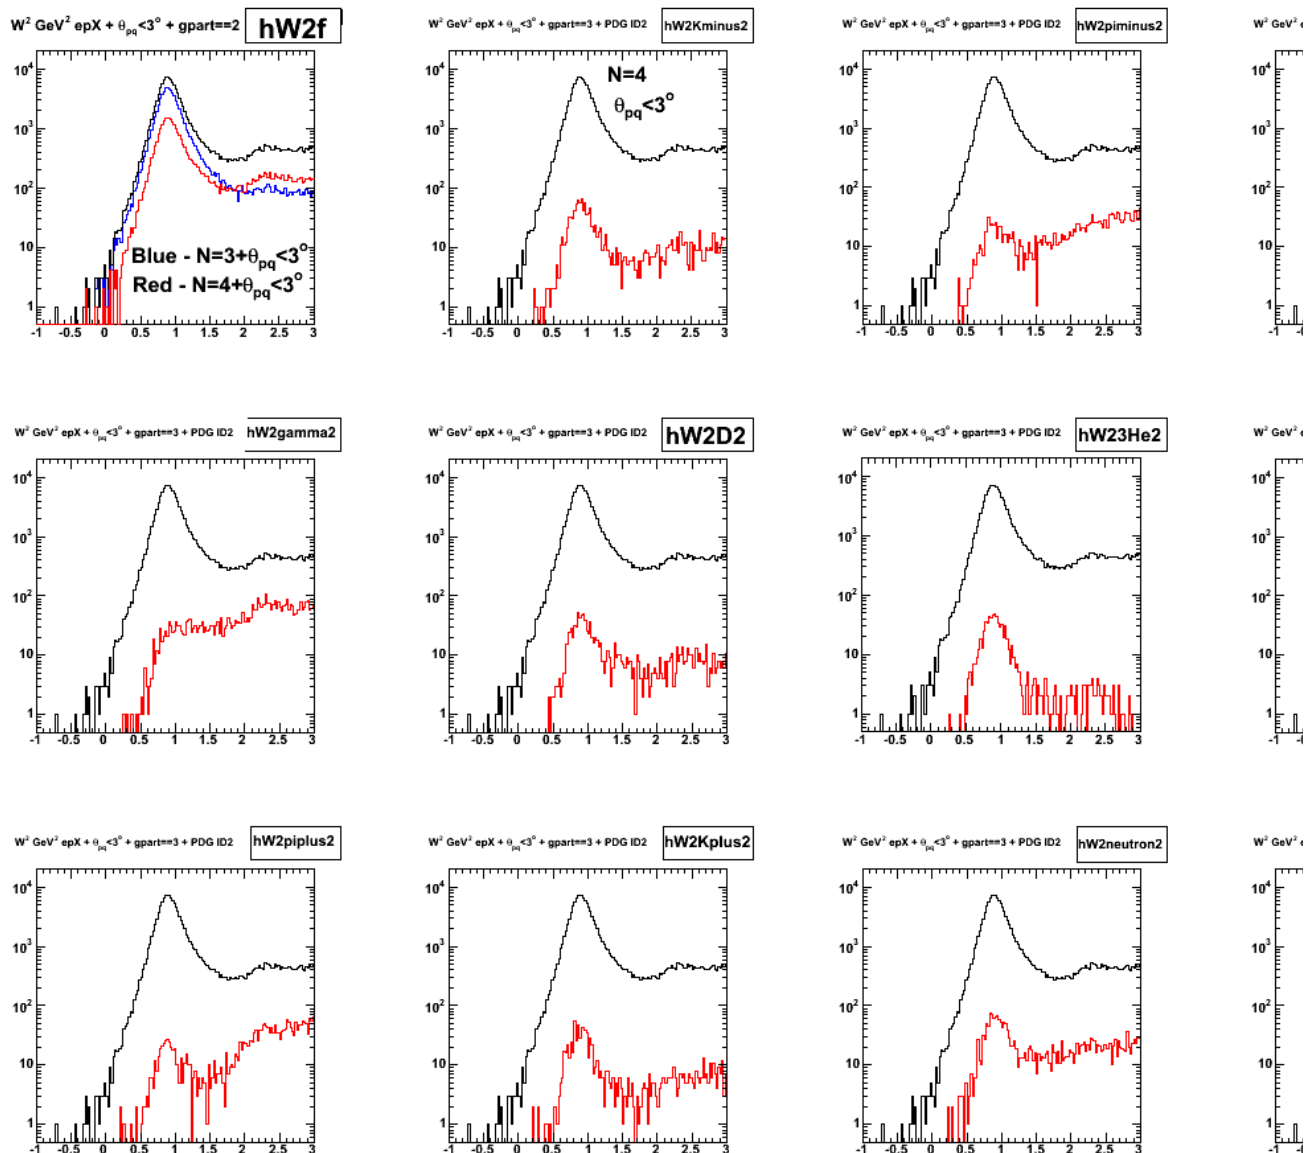

Now take the N=2 events and add in the N=3 events from the top 8 channels (K-,K+,neutron, proton, D, 3He, 4He, and id=0) and we recover most of the events lost to the N=2 cut (red/black = 0.82, blue/black=0.64).

2009-12-26 00:11:56

Fig 5. Comparison of W2 for θ_{pq} cut only (black) with the N=2 cut (blue) and the N=2+N=3(K-,K+,neutron, proton, D, 3He, 4He, and id=0)

Now look at the next level of coincidences (N=3).

2009-12-26 00:36:38

Fig 6. Effect of requiring $N=4$ and $\theta_{pq} < 3$ deg. The labelling is wrong. It should be $gpart==4$, not $gpart==3$.

2009-12-26 11:12:41

Fig 9. Distribution of the number of tracks in each event. Require ep events so gpart >= 2.

Now consider the effect of the hermiticity cut without the θ_{pq} cut. The goal here is to demonstrate the power of the hermiticity cut for removing inelastic events even though it is not needed at these low 4-momentum transfers. The first plot below (Fig 10) shows in the left-hand panel the W^2 distribution for epX events (black), $epX + \theta_{pq} < 3^\circ$ events (red), and $epX + N=2$ events (green). Heer the hermiticity cut has already reduced the size of the QE peak below what we would obtain for the θ_{pq} cut alone. In analogy with what I did above, I added the results of the hermiticity cuts for $N=2$ and $N=3$ together to obtain the blue histogram in the left-hand panel. It is not clear here that this improves things. The QE peak now exceeds the result using just the θ_{pq} cut, but the background is noticeably larger and may well account for the increase in the QE peak with the $N=(2 \text{ or } 3)$ cut versus just the $N=2$ cut in the left-hand panel.

$W^2 \text{ GeV}^2 \text{ epX}$

2009-12-26 12:02:08

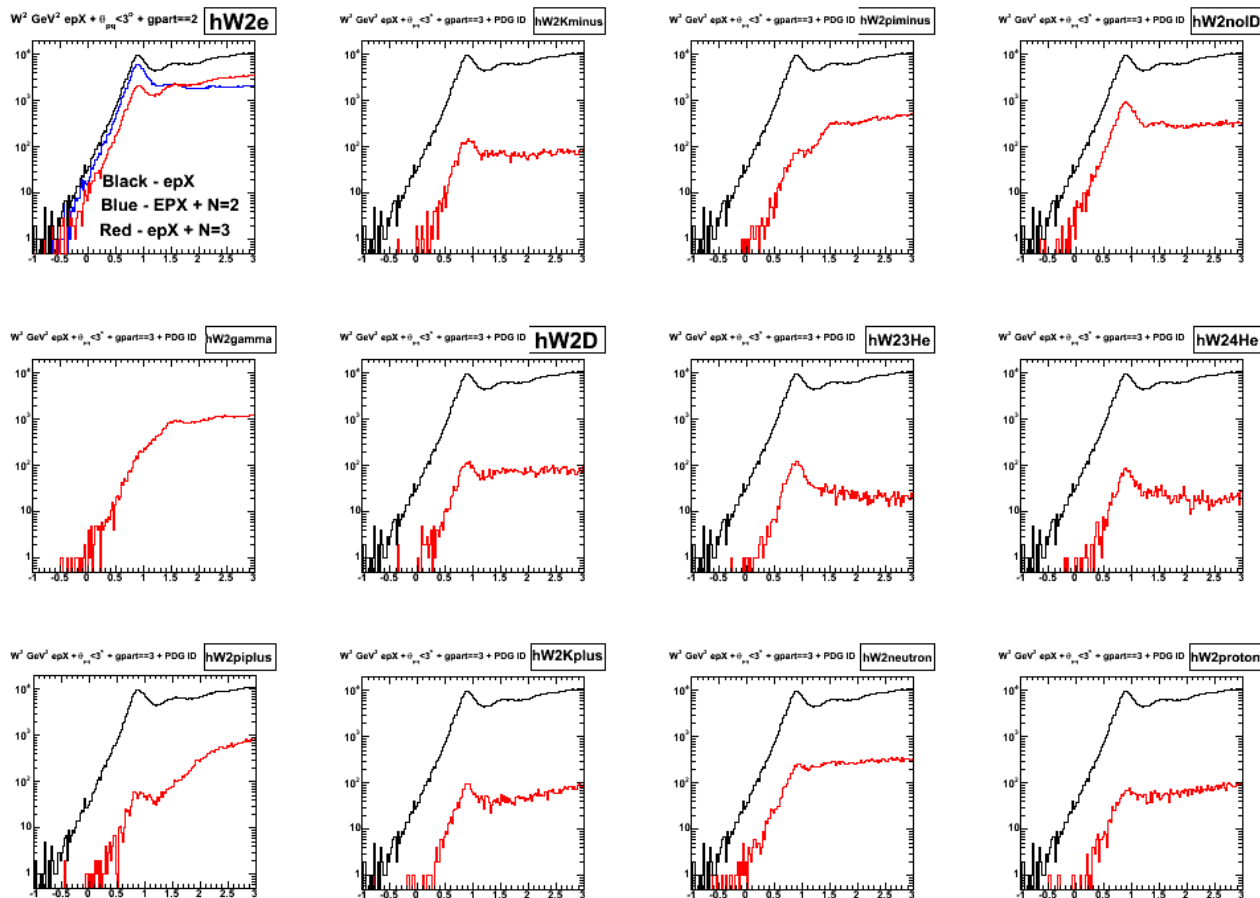

Fig 10. Comparison of W^2 distributions in the left-hand panel for epX events (black), $epX + \theta_{pq} < 3^\circ$ (red), and $epX + N=2$ (green). In the right-hand panel we show the W^2 distribution for $epX + (N=2 \text{ or } N=3)$ events (blue).

Click [here](#) to view the object (ROOT macro for the left-hand panel only) you uploaded.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The next plot (Fig 11) shows the W^2 distributions for a variety of cuts. In the upper, left-hand panel we compare the distribution for epX events with no hermiticity cut (black) to the distribution for the $N=2$, hermiticity cut (blue). The number of QE events appears to go down, but there is a greater drop in the number of inelastic events. Applying the $N=3$, hermiticity cut gives the red histogram. Here the effect is much less dramatic. In fact, the shape is roughly the

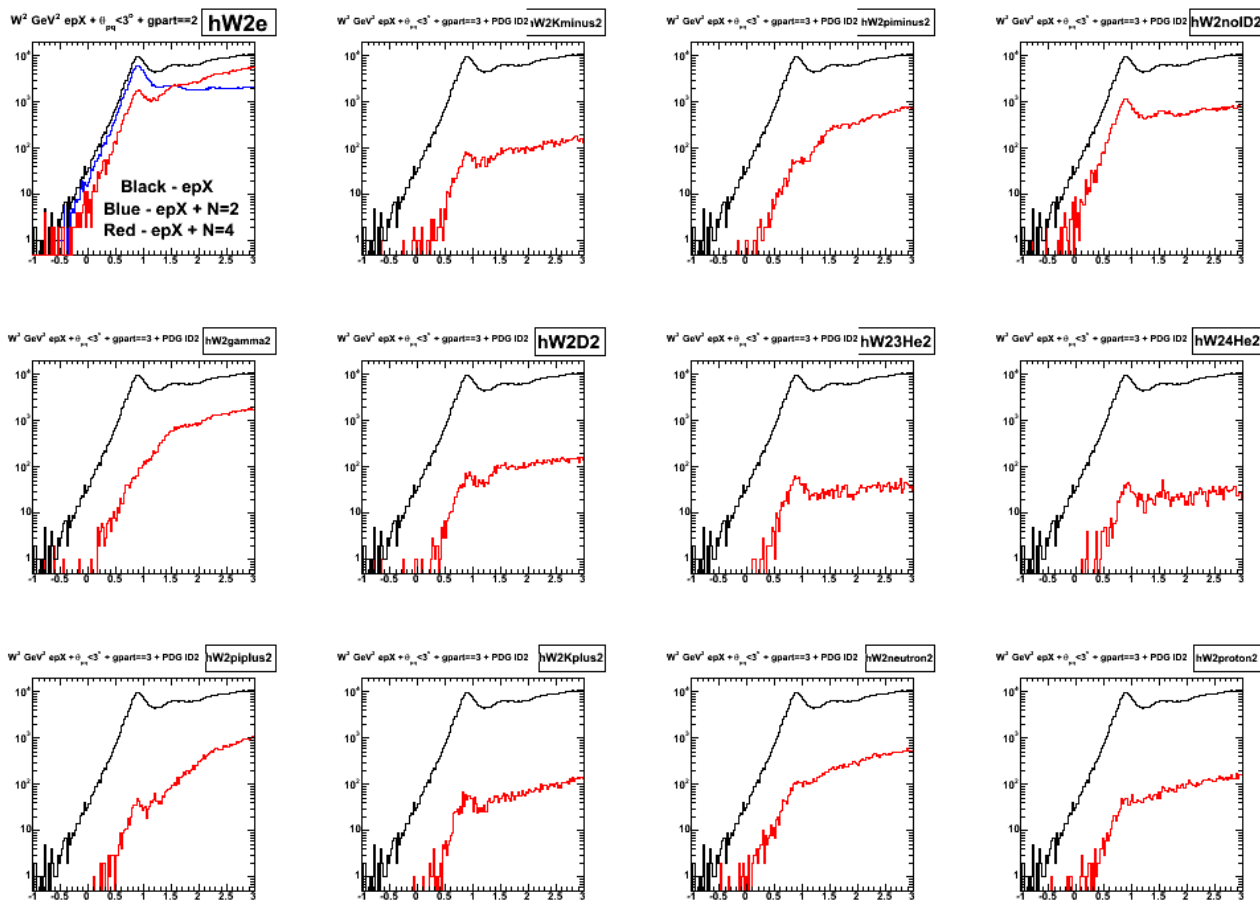

same across the W2 range. The channels that show the most prominent QE peak are K-, id=0, D, 3He, 4He, and K+. Unlike the results above (Fig 3 and Fig 6) where we also had the θ_{pq} cut on, the proton and neutron channels do not show a very distinct QE peak.

2009-12-26 11:20:00

Fig 11. Comparison of epX events and epX+N=3 events. The upper left-hand panel also shows the results for epX+N=2 events.

Now look at the distributions for epX+N=4 events since these made up a significant (about 10%) contribution when I had the θ_{pq} cut also turned on. These W2 distributions do not have the prominent QE peak like they did when I had the θ_{pq} cut turned on so I won't bother adding them to the N=2+N=3 distribution.

2009-12-26 12:22:00

Fig 12. Comparison of epX events and epX+N=4 events. The upper left-hand panel also shows the results for epX+N=2 events.

Jerry Gilfoyle's Enotebook page 304 - Testing the hermiticity cut on the E5 data. (Jerry Gilfoyle)

[Modified Sun Dec 27 01:07:22 2009 (GMT) Jerry Gilfoyle]

At Kawtar's suggestion I have investigated the effect of the hermiticity cut on the 4.2-GeV, E5 data set. I don't think we need to put this in the update or in the main presentation, but it would be good to be prepared for questions from the PAC. In our presentations of the impact of the hermiticity cut we usually show the effect of the θ_{pq} cut first followed by applying the hermiticity cut. For the E5 data, we know the θ_{pq} cut does an excellent job reducing the inelastic background by itself so here I show the effect of the hermiticity cut first and then apply the θ_{pq} cut. The inelastic background in Fig 1 under the black histogram is dramatically reduced by requiring two particles (e-p) in the final state. In the region $W^2 < 1.2 \text{ GeV}^2$, the number of background events is reduced by a factor of three in going from the black histogram (no hermiticity or θ_{pq} cut) to the red one (hermiticity cut turned on). This drop is roughly consistent with our simulation results at higher Q^2 . I could redo our simulations at this Q^2 , but that would require using GSIM instead of FastMC12 to compare with the E5 data (which is a big job). The hermiticity cut sharply reduces the inelastic background even at lower ($< 5 \text{ GeV}^2$) even though it is not needed in that Q^2 range.

Fig 1. Plot for PAC35 update showing W^2 distribution without hermiticity or θ_{pq} cut (black), with just the hermiticity cut (red), and with both hermiticity and θ_{pq} cuts.

Now for the 'bad' news. The plots below compare the effect of the θ_{pq} + hermiticity cuts with just the θ_{pq} cut alone. The left-hand panel in Fig 2 shows the effect first of the θ_{pq} cut alone (red histogram) followed by the addition of the hermiticity cut (green histogram) where we veto events with $N > 2$ where N is the number of tracks. The surprise here is that the hermiticity cut removes more than half of the quasielastic (QE) events. In the right-hand panel modifying the hermiticity cut from $N > 2$ to $N > 3$ restores most of the lost QE events, i.e. we include ep events with another particle in the final state. The number of epX events with $X = \text{neutron}$ is small so the disparity in the number of events between the red and green histograms in the left-hand panel of Fig 2. does not seem to be due to quasielastic epn events. This would imply we have a significant number of random coincidences associated with the ep events. Notice also there are differences between the plots in the number of events for nominally the same conditions. I have been struggling with some dying nodes in my cluster and will try and get those distributions consistent with one another in the next couple of weeks.

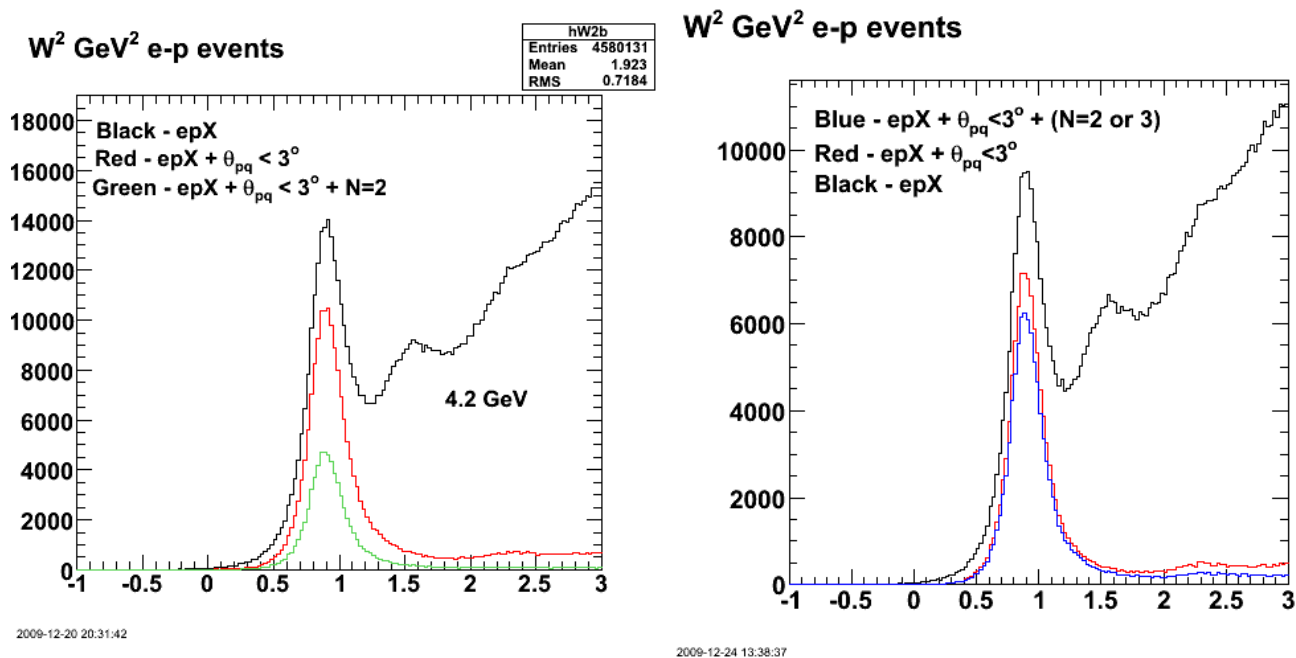

Fig 2. The left-hand panel shows the effect of the θ_{pq} cut on the W^2 distribution for epX events (red) followed by adding the hermiticity cut (no $N > 2$ tracks). The right-hand panel shows the W^2 distribution if the hermiticity cut is changed to a veto of events with the number of tracks $N > 3$ (blue).

Next I went searching for the lost QE events. To make a long story short, I looked at the different final channels for $N=3$ and $N=4$ particles in the final state. If I astutely choose those final states and add them to the green histogram in the left-hand panel of Fig 2, I can get back to 94% of the red histogram (which has only the θ_{pq} cut and not the hermiticity cut). The results are shown in Fig 3. The red histogram is for epX events with the θ_{pq} cut alone. The blue histogram shows the results for epX events with $\theta_{pq} < 3$ deg + ($N=2$ or $N=3$). The green histogram shows the results epX events + $\theta_{pq} < 3$ deg + ($N=2$ or $N=33$ ('best' channels) or $N=4$ ('best' channels)). 'Best' here is determined by looking at the W^2 distribution for a particular final state (e.g. epK+) and picking out the channels with prominent quasielastic peaks. Applying the hermiticity cut is going to be more complicated than we originally thought and will require a better understanding of the random coincidences.

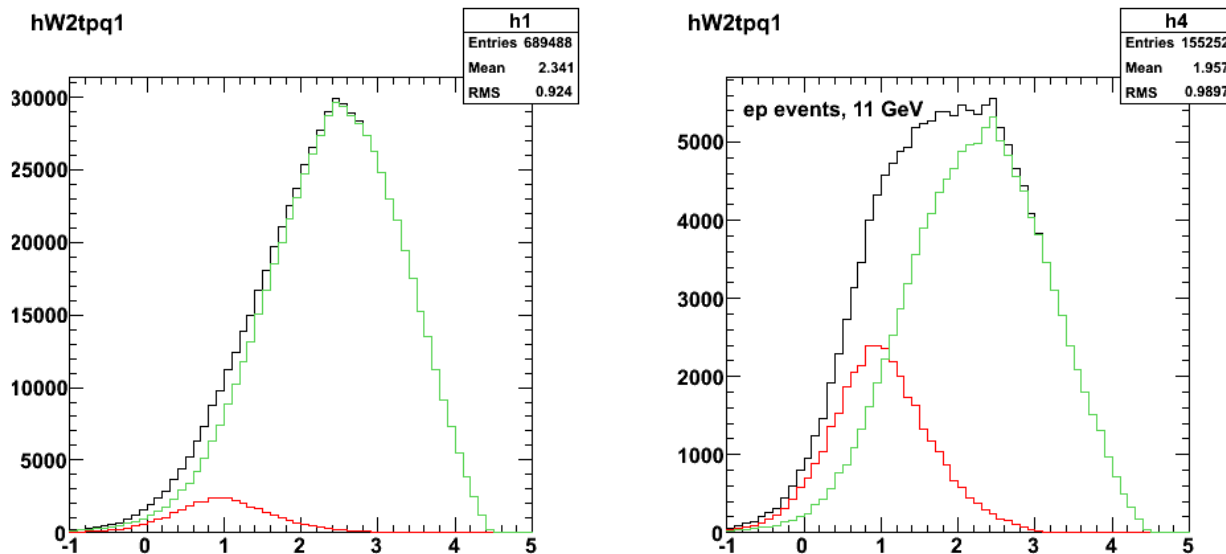

Fig 3. Finding more of the missing QE events. The red histogram is for epX events with the θ_{pq} cut alone. The blue histogram shows the results for epX events + $\theta_{pq} < 3$ deg + ($N=2$ or $N=3$). The green histogram shows the results epX events + $\theta_{pq} < 3$ deg + ($N=2$ or $N=33$ ('best' channels) or $N=4$ ('best' channels))

Jerry Gilfoyle's Enotebook page 305 - Effect of reducing the θ_{pq} on the inelastic background (gpg)

[Modified Mon Jan 4 16:27:59 2010 (GMT) gpg]

The first two plots below show the starting point for this study. Figs 1-2 show the progression of cuts from Fig 7-8 of entry [301](#) for $\theta_{pq} < 1.5$ deg along with the results of integrating over the range $-1 < W_2 < 1.2$ GeV².

2009-12-31 20:45:00

Fig 1. Same as Fig 5 in entry 301 for ep events, but run with submit_gmnsim.pl 11000 400000 1, theta_pq < 1.5 deg, F=0.33.

Jerry Gilfoyle's Enotebook page 306 - Investigating the N=3 tracks for the hermiticity cut (gpg)

[Modified Wed Jan 6 20:54:05 2010 (GMT) gpg]

Let's look at the properties of the tracks that have ID=0 and come with the QE ep events in the 4.2-GeV data set. The first plot on the left-hand side below shows the distribution of charges for tracks with N=3 and ID=0. There are lots of tracks with all three charges so there is little reason to filter there.

Fig 1. Charge distribution (left-hand panel) and vertex distribution for tracks from events with N=3 and have e+p. The right-hand panel shows the vertex distribution for the same events.

Jerry Gilfoyle's Enotebook page 307 - Study out-of-time tracks (gpg)

[Modified Wed Jan 20 15:15:49 2010 (GMT) gpg]

It looks like there may be a lot of out-of-time tracks (status = 0 for the track in the evt bank. This is due to tracks from a previous or later beam bucket where the electron was undetected, but the proton (most likely) or pi+ left a track. The first plot shows the effect of turning on the requirement that $\text{abs}(\text{status}) > 0$ so there should be no out-of-time tracks in the blue histogram. Most of the ID=0 tracks disappear, but large fractions of the other final states remain.

2010-01-11 23:20:01

Fig 1. Distribution of PDG particle IDs for the third and higher tracks (not the electron or proton track) for $W^2 < 3.0 \text{ GeV}^2$ and other, standard ep cuts.

Click [here](#) to view the object (ROOT macro) you uploaded.

2010-01-11 23:43:08

Fig 2. Same as Fig 1, but now add the requirement $\text{abs}(\text{dvz}) < 1.5 \text{ cm}$ where $\text{dvz} = \text{vz}[\text{electron}] - \text{vz}[\text{iparticle}]$ which is the distance between the vertices of the electron and the $N > 2$ track.

Click [here](#) to view the object (ROOT macro) you uploaded.

Consider the plot below. Upper left and Upper right panels compare the W^2 distribution for several different cuts. The lower left looks at the difference between phi for the electron and phi for the $N > 2$ tracks. The wide peak at $\hat{\Gamma}^1 = 180 \text{ deg}$ may be a sign of ghost tracks according to Stepan associated with the proton. The peak at 0 deg may be ghosts associated with the electron. The lower right panel shows the $\hat{\Gamma}^1$ angle of the $N > 2$ tracks. The large peak near zero is

unexplained.

Click [here](#) to view the object (ROOT macro) you uploaded.

In the next plot I add up the histograms from fig 6 above (red hist) which includes events with N=3, third track is out-of-time (OOT), and its vertex is more than 1.5 cm away from the electron vertex. This histogram has lots of inelastic events at high W2 and using the W2 dists in fig 6 as a guide exclude the gamma hist from fig 6 in the sum. This gives me the black curve which has fewer inelastics and close to the same number of QE events. The blue curve is the result for requiring N=2 and the green requires theta_pq < 3 deg only.

Fig 7. Adding up this histograms. See text just above.

Click [here](#) to view the object (ROOT macro) you uploaded.

Add up the 'N=3 + OOT + no-vertex - gammas' distributions and add them to the N=2 and compare with the theta_pq only dist. The summed histogram now exceeds the theta_pq-only one which it should, but probably by not enough. Ultimately I need to compare the theta_pq-only with theta_pq+summed histogram and hopefully get the same number of QE events.

Fig 8. Comparison of theta_pq-only events and the ones from N=2 + N=3 should have been!!

Click [here](#) to view the object (ROOT macro) you uploaded.

Get the full 148 runs into the data; same analysis as above.

Click [here](#) to view the object (ROOT histogram file) you uploaded.

The plot below shows some neat results. The black histogram is W^2 with just the \hat{I}_{pq} cut and no hermiticity cut. We want to reproduce the size of the QE peak with the hermiticity cut turned on so we are confident it is not distorting things. We also want to reduce the inelastic background at higher Q^2 . We know from before that setting the hermiticity cut to $N=2$, we lose a large fraction of the QE events. This is the red histogram in the plot which requires $\hat{I}_{pq} < 3$ deg and $N=2$. The loss of QE events that occurs when the hermiticity ($N=2$) cut is turned on is due to a broad definition of what is a track in SEB. I opened up the hermiticity cut to include events with $N>2$ + (out-of-time tracks) + ($dvz > 1.5$ cm) where dvz is the difference between the electron vertex and the vertex of the extra track. These are all tracks that are not associated with the e-p events so we don't want them in the sample and we don't want them to veto the e-p event. The W^2 distribution for these events is the set of blue points. When I add these 'opened up' hermiticity cut points (blue) with the original ' $N=2$ ' points (red) I get the green points in the figure. These closely match the black histogram which is just the \hat{I}_{pq} points near the QE peak and are about a factor of two less in the inelastic region at higher W^2 . The black points are W^2 for events with ' $N=2$ ' and ' $N>2$ ', but no \hat{I}_{pq} cut.

2010-01-13 18:38:39

Fig 9. Starting to get things reasonable. See text above.

Use the gpart>2 in the analysis and described just above so we catch all the ep with additional tracks that are out-of-time or out of the vertex cut.

2010-01-14 00:21:17

Fig 10. See text below.

Click [here](#) to view the object (Root macro) you uploaded.

1. For the CLAS6 data, the hermiticity cut is not needed. This cut reduces the already small inelastic background (compare black and red histograms).
2. Without requiring $\hat{I}_{pq} < 3$ deg, the hermiticity cut still dramatically reduces the inelastic background (compare blue and green histograms.)
3. Hermiticity cut here includes ep events with additional out-of-time tracks or ones that fall outside the vertex cut (1.5 cm).

BIG STUPID!!! The problem with the previous plot is that there are more QE events when I apply the \hat{I}_{pq} cut + hermiticity cut than when I apply the \hat{I}_{pq} cut alone. This makes no sense. The problem is that I was generating the W2 spectra in coincidence with a wide range of particles and then adding them together. If I had more than two additional tracks beyond the ep tracks and there were two or more of those tracks that had out-of-time tracks and failed the vertex cut, then I was double (and higher) counting. This is why I was getting two many events when I applied the modified hermiticity cut. The next plot shows this more clearer where I now required any track with $N > 2$ and did not use $N = 3 || N = 4 || \dots$

GGGAAAGGGHHHH!!!!

Jerry Gilfoyle's Enotebook page 308 - Background inelastic events subtraction (gpg)

[Modified Wed Jan 20 15:18:49 2010 (GMT) gpg]

In preparation for the update talk I studied again the background subtraction of the inelastic events. I cheated like crazy to do this, but it's a start. My method is the following.

1. Fit the QE and inelastic spectra separately for the $Q^2=12.5-14$ GeV² bin just using a gaussian in each case and over the range $W_2 = -1 \rightarrow 5$ GeV². The simulated data I used are in `gmn/background/bgnd1.C` which is a long statistics run.
2. Do another, low statistics run (actually I used the same command I used to generate the histograms in `bgnd1.C` and then used the output from just node 0). Fit the results with the gaussians from step 1 scaled by a factor. The two factors (one for QE gaussian and one for the inelastic gaussian) are the only parameters.
3. Some results are below. The coefficient in front of each gaussian should be $0.217=4372/20167$ which is the ratio of the number of events in the low-statistics W_2 spectrum to the number of events in the W_2 used to generate the original fits (see 1). Things are not too crazy until the upper limit on the range of the fit gets small ($W_2 < 1.2$ GeV²). At this point we are not fitting beyond the peak in the distribution and the fit coefficient uncertainties get very large. With a 'reasonable' choice of the upper limit on W_2 , the results for the background fit are within 10% of expected value which is within our stated uncertainty in the update. I still have to think about how valid this result is???? Presumably with real data we would use a `gemc` simulation tuned to various parts of our data (i.e. get the W_2 distribution for QE ep events using a missing mass cut to eliminate more of the background, get the W_2 distribution for inelastic events using a coplanarity cut to eliminate the QE events, ...) to get the shapes of the QE and inelastic W_2 distributions. We then fit these results like I just did with a single coefficient for each component.

See log entry for 10-jan-19 for more details.

sample	coefficient	coefficient/0.217	W2 range
QE	0.186 +/- 0.005	0.86	-1 -> 5 GeV ²
IN	0.272 +/- 0.008	1.26	
QE	0.195 +/- 0.006	0.90	-1 -> 2 GeV ²
IN	0.229 +/- 0.008	1.06	
QE	0.195 +/- 0.008	0.90	-1 -> 1.6 GeV ²
IN	0.229 +/- 0.040	1.06	
QE	0.170 +/- 0.012	0.78	-1 -> 1.2 GeV ²
IN	0.479 +/- 0.103	2.21	

4. Next fit the high-stats simulations of the QE and inelastic events with a different function. Use a chi-square distribution defined in the following way in ROOT.

```
TF1 *fit12 = new TF1("fit12", "[0]*( 462.993*((x+1)**4.28753)*exp(-(x+1)**2/1.63897) ) + [1]*( 5.89402*((x+1)**6.48052)*exp(-(x+1)**2/2.91073) )",
```

Next, use the function above to fit a low-stats W_2 spectrum containing both QE and inelastic events. Some fit results are below too.

sample	coefficient	coefficient/0.217	W2 range
QE	0.188 +/- 0.005	0.87	-1 -> 5 GeV ²
IN	0.273 +/- 0.008	1.26	
QE	0.197 +/- 0.006	0.87	-1 -> 2 GeV ²
IN	0.228 +/- 0.019	1.05	
QE	0.196 +/- 0.007	0.90	-1 -> 1.6 GeV ²
IN	0.239 +/- 0.034	1.10	

See plot below for fit example.

2010-01-20 09:43:43

Fig 1. Fit results using chi-square distribution. See log entry log-10-jan-19 for fit results.

Click [here](#) to view the object (ROOT macro) you uploaded.

- Now calculate the integrals and compare with the actual histogram for the inelastic contribution. This looks quite good, but then again it should since we fit with curves derived from the same simulation.

Function	Range (W2)	Integral	Histogram	% diff
chi-square	-1->1.6	41.8	41.1	1.7
gaussian	-1-<1.6	41.0	41.1	0.2
chi-square	-1->2.0	68.5	70.3	2.5
gaussian	-1->2.0	68.7	70.3	2.3

Jerry Gilfoyle's Enotebook page 309 - Hermiticity of CLAS12 (Mac question) (gpg)

[Modified Fri Jan 29 01:19:54 2010 (GMT) gpg]

In the preparation for the update talk, Mac made the comment that the hermiticity cut looked too good. There was no effect on the QE peak which is true because we treated the inelastic and QE events completely separately. There are no 'true' background events where a QE event has additional, background tracks. Instead, we studied this question by looking at events with this type of background in the 4.2 GeV, E5 data. See entries 302-304, 306-307 in elog. The second point was that it was highly effective, i.e. it reduced the inelastic background by a factor of 5-10 (depending on W2) when applied without the θ_{pq} cut which is a much greater effect than when the same technique is applied to the 4.2-GeV, E5 data. See entries 302-304, Fig 11b in entry 307. Will speculated that the effect is due to the greater hermiticity of the CLAS12 relative to CLAS6. To study this, first look at the cross section effects. There may simply be many more events with three-particle or more final states for $E = 11$ GeV and $E_{q2} = 12.5-14.0$ GeV2 so the hermiticity will have a bigger effect. We look at FastMC12, but at low (4.2 GeV) beam energy and small Q2. If the hermiticity cut is still very effective, then that would support the higher-hermiticity of CLAS12 as the answer. If the effectiveness of the hermiticity cut drops a lot, then that would support the larger-number-of-three-particle-or-more-final-states at large Q2 hypothesis.

Below are the results for the default 11 GeV calculation.

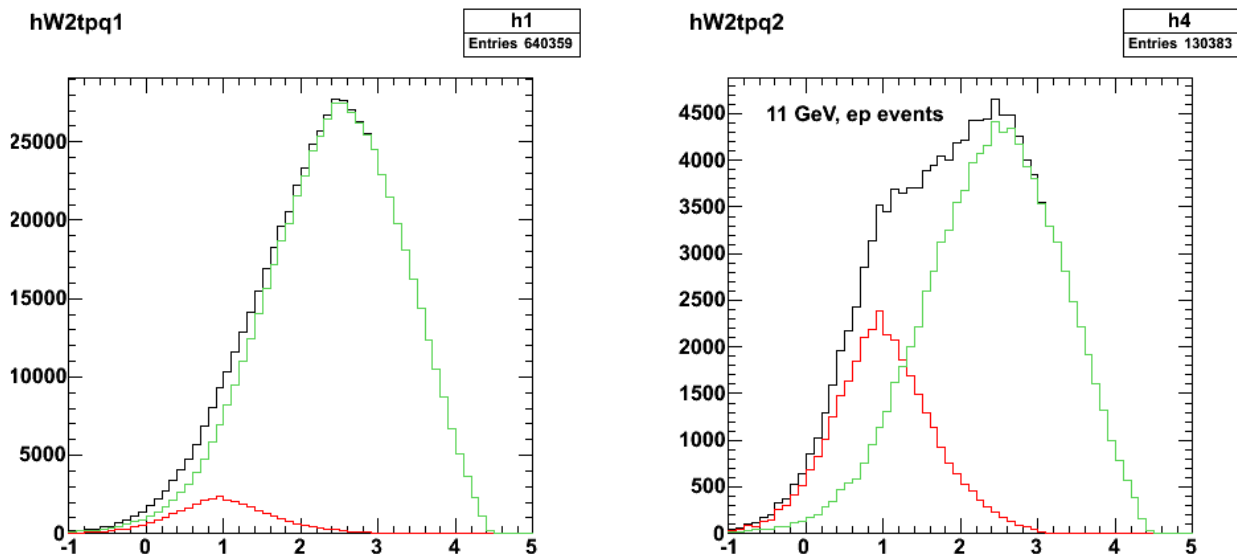

2010-01-25 09:18:00

Fig 1. en events for 11 GeV, $Q^2=12.5-14$ GeV2. Use `submit_gmnsim.pl 11000 400000 1` to run with $\theta_{pq} < 1.5$ deg, $F=0.33$.

Figures 3-5 show the effect of the θ_{pq} and hermiticity cuts calculated using queeg-genevD-FastMC12 for the same kinematics (Q2 and Ebeam) as the E5 data shown in entry 307 (e.g. fig 11b). At the lower beam energy the calculation of the impact of the hermiticity cut is vastly reduced compared to its effect at higher Q2 as shown in Figs 1-2. After discussing with Mac we think the cause of this effect is the much smaller acceptance for the background events (π^+/π^- mostly) in CLAS12 at lower Q2 and beam energy. As an example consider the plots below. The first (fig 6) shows the $e\text{-}\pi^0$ acceptance for $E = 11$ GeV, $Q^2 = 12$ GeV2 as a function of π^0 momentum vs. π^0 angle in the lab in degrees. This is what we would expect for the CLAS12 GMn measurement at the high Q2 end. Filenames for following plots are qsq2.ps and qsq12.ps.

Fig 6. Geometric acceptance of CLAS12 for e-pi0 at E = 11 GeV, Q2 = 12 GeV2.

The next figure (fig 7) shows the same CLAS12 e-pi0 acceptance, but now for E = 5 GeV and Q2 = 1.2 GeV2. Notice that the accepted momentum range is much reduced and the 'hole' at forward angles and small momentum. We are not doing as well detecting pi0's. If the efficiency/acceptance of pi0's is diminished relative to the high E/Q2 kinematics, then the hermiticity cut will not be as effective. This is what is seen in the FastMC12 simulation.

Fig 7. Geometric acceptance of CLAS12 for e-pi0 at E = 5 GeV and Q2 = 1.2 GeV2.

Jerry Gilfoyle's Enotebook page 310 - Fix EC position in gemc (gpg)

[Modified Fri Feb 5 13:26:24 2010 (GMT) gpg]

In going back over the geometry for the EC, I found an error. The position of the mother volume was defined with this command in

```
/u/home/gilfoyle/gemc/production/database_io/clas12/geo/ec/ec_build.pl
```

. \$detector{"pos"} = "0*mm 2156.71*mm 1957.8*mm"; where the first number is the position of the center of the mother volume in the x direction (transverse to the beamline), the second number corresponds to the perpendicular distance from the beamline to the center of the mother volume which we have picked to be in the y direction, and the third number is the position of the center of the mother volume along the beam line from the CLAS12 target minus the infamous 5.0 m. For the third number I previously had 2217.23*mm which is the perpendicular distance from the CLAS12 target to the upstream face of the EC. First figure below is the old, incorrect (?) geometry.

Fig 1. EC with old z position.

Fig 2. EC geometry with modified z position of mother volume.

Starting to look good. The clipped lead is a small, but visible effect in plot below.

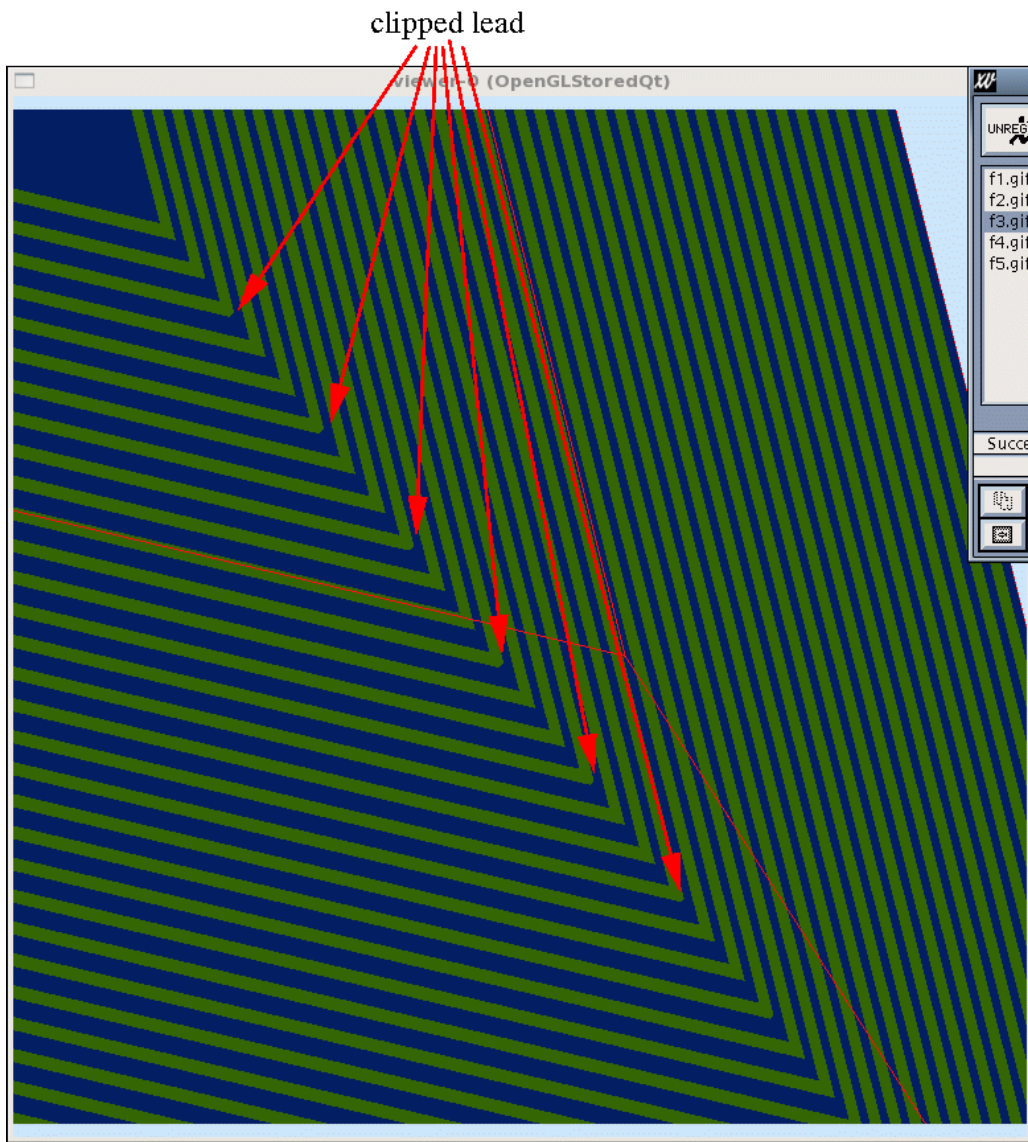

Fig 2. target side view of ECs showing clipped ends on the lead sheets on every third layer of lead.

Fig 3. Another view of the EC showing clipped lead sheets.

Jerry Gilfoyle's Enotebook page 312 - Strips and digitization of EC events in gemc (gpg)

[Modified Wed Feb 24 02:18:56 2010 (GMT) gpg]

The plot below shows an early plot of events in the EC simulated with gemc after putting in the strips and digitizing the ADC and TDC.

Fig 1. Local x versus local y. What do I only see hits in a single sector (because it's all local coordinates so the events from different sectors are plotted on top of each other)? The electrons are 8 GeV at $\theta = 10$ deg, $\phi = 0$ deg.

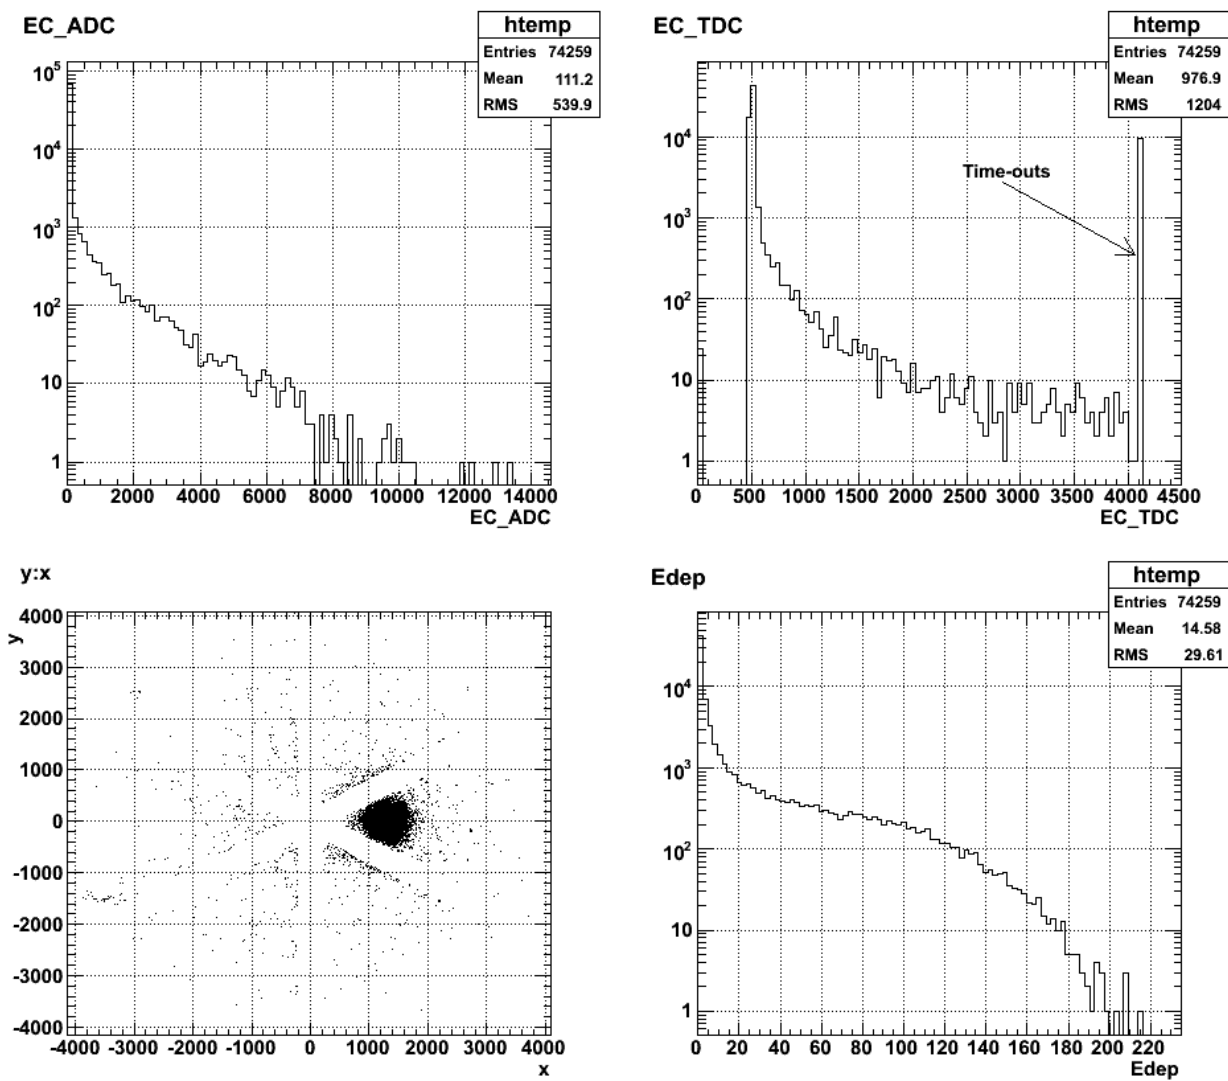

Fig 2. Plots of run with 500 events.

Jerry Gilfoyle's Enotebook page 313 - Systematic uncertainty due to radiative effects (gpg)**[Modified Wed Feb 24 02:53:56 2010 (GMT) gpg]**

To estimate the effect of radiative corrects on the ALTp analysis I am investigating the difference in the EXCLURAD calculations for different helicities. The hope is that the difference between the between the radiative corrections for the two helicities is very small so that in the asymmetry (which is essentially a ratio), any differences will cancel.

First calculation using the output of deep to get the standard results for each helicity. Code is below.

```
c now translate these structure functions into the form used by
c Afanasev et al. the notation here is taken from Gross and
c Dmitrasinovic, PR C40, 2479 and J.Adam, et al nucl-th/0204068.
c see notebook eod7.
```

```

Md2 = (Md)**2
W2MeV = W**2
W2 = (W*1.0e-03)**2

MdMeV = 1.876*10**3

Jerry Gilfoyle's Enotebook page 316 - Sampling Fraction in EC (gpg)

[Modified Thu Mar 11 13:11:30 2010 (GMT) gpg]

Investigate the sampling fraction in the gemc EC simulation in the following way.

1. Extract histogram of Edeps for N=50 electron events using the following command to run gemc(for 2 GeV)

```
gemc -gcard=modified2.gcard -DATABASE=user_geometry -BANK_DATABASE=user_banks -N=50 -BEAM_P="e-, 2.0*GeV, 10.0*deg, 0*deg" -OUTPUT="evio, EC1.ev"
```

Then in root:

```
TFile *f1 = new TFile("EC1.root")
TH1D *hEdep1 = new TH1D("hEdep1","E_{dep} for electrons",180,0,180)
ect->Draw("Edep>>hEdep1","t<100 && pid==11 && Edep>0 && lx>-100 && lx<100 && ly>-1200 && ly<-800")
```

2. This distribution holds all the Edep in all the hits for the 50 electrons so take the product (number of events in each bin)*(energy of bin) and sum over all bins. For N=1 this would just be the total deposited energy of the electron so for N=50 divide by 50.
3. this is now the average deposited energy per electron so divide this number by the original electron energy (2 GeV or 4 GeV)

I did this for $p = 8$ GeV and got $f = E/p = 0.242$. For $p = 2$ GeV I got $f = 0.245$ (see Figs 1-2). The calculates are below.

Click [here](#) to view the object (Mathematica notebook) you uploaded.

2010-03-08 10:01:36

Fig 7. Require an energy threshold in the energy deposited in the EC and you get the turn-down at low electron momentum. Otherwise, this is the same as Figure 6.

2010-03-08 10:19:33

Fig 8. Combine Figs 6-7 for comparison.

Click [here](#) to view the object (ROOT macro) you uploaded.

2010-03-08 11:03:30

Fig 9. After talking with Stepan and Hovannes, the uncertainties still look to be too large on each point. Just for fun, throw in another binomial factor in the variance ($p*(1-p)$) and it looks better, but still not great.

Click [here](#) to view the object (ROOT macro) you uploaded.

Neither of the above approaches give reasonable uncertainties. Follow Hovanes's suggestion to generate the distribution of total $E = \text{sum}(\text{all } E_{\text{deps}})$ for many events and take the centroid and width. That seems to work and gives much smaller uncertainties.

2010-03-08 14:25:20

Fig 10. Sampling Fraction with uncertainties based on the distribution of E_{total} for many events at each electron momentum.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now put in the attenuation in the scintillator.

Fig. 11. Effect of attenuation length. This is much larger than expected from the EC NIM paper (see plots above), but it may be explainable because these are all events at a single angle and thus a nearly fixed, large attenuation.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (tar archive of Root Tree files) you uploaded.

Jerry Gilfoyle's Enotebook page 317 - Resolution in gemc and comparison with GSIM (gpg)

[Modified Tue Mar 9 17:10:50 2010 (GMT) gpg]

Calculate the resolution by collecting histograms of sampling fraction as a function of electron momentum. Use the RMS width at the resolution. See the plots below.

Fig 1. Resolution as a function of p_e with no threshold and with $E_{dep} > 1.0$ MeV.

Sampling fraction and resolution from EC NIM paper.

Sampling fraction and resolution fro

Jerry Gilfoyle's Enotebook page 318 - Position resolution in gemc (gpg)

[Modified Tue Mar 9 03:12:45 2010 (GMT) gpg]

Use a similar setup to the previous entry, use electrons at $\theta=25$ deg, $\phi = 0$ deg, and no field (so the electron strikes the face of the EC at a right angle). Project out ly vs. lx and get the width of the central region. See the plot.

Fig 1. Resolution in lx for $p_e = 10$ GeV/c electrons.

Click [here](#) to view the object (ROOT macro) you uploaded.

Jerry Gilfoyle's Enotebook page 319 - Position resolution, shower size, and Plots for Collaboration meeting (gpg)

[Modified Tue Mar 16 20:18:16 2010 (GMT) gpg]

Use a similar setup to the previous entry, use electrons at $\theta=25$ deg, $\phi = 0$ deg, and no field (so the electron strikes the face of the EC at a right angle). Project out ly vs. lx and get the width of the central region. See the plot.

Fig 1. Resolution in lx for $p_e = 10$ GeV/c electrons.

Click [here](#) to view the object (ROOT macro) you uploaded.

Plots below for the Collaboration meeting next week. The expectation is that 95% of the energy of the shower lies within 2 cm of the hit according to the EC NIM paper.

Fig 2. What are those side peaks?

```

TH1D *hlx = new TH1D("hlx","lx",1000,-500,500)
ecT->Draw("lx>hlx","t<50")

```

Stepan thinks we are seeing the effect of the strips in the EC. The side peaks are at ± 70 mm which is about the width of the pixels in the EC. This makes sense

because we are projecting down onto the x axis. The pixels in the EC are horizontal triangles with the vertex at the top or bottom. Even with a uniform distribution of events you would get peaks when you did the projection because there is more area to project down the center of the triangle than on the edges. Imagine a triangle like the one below. Break it up into vertical strips and calculate the area of each strip.

The area will increase as you go from left to right until you reach the apex of and then the area will go down again. The area of these strips multiplied by the average occupancy (number of events) on each strip will give you the projection of the number of events along the horizontal (i.e. x) axis. Even a uniform distribution then will have a peak in the middle.

2010-03-09 14:36:00

Fig 3. Fit results for width of shower.

Click [here](#) to view the object (ROOT macro) you uploaded.

2010-03-09 14:57:03

Fig 4. Trying to squeeze down the transverse size.

The EC NIM paper says that the transverse width of the shower is +/- 2cm and contains 95% of the shower. I assume this means the energy of the shower (see plots above). I make a plot of the energy deposited in the EC as a function of ix (see below). For a threshold of 5 MeV, I get the 95% for $p_e=4$ GeV (see energyDist1.C for the Root code).

Fig 5. Distribution of total deposited energy as a function of x .

Click [here](#) to view the object (ROOT macro) you uploaded.

Integral of deposited energy for fig 5.

```
root [48] float low=hEdist->Integral(1,979)
root [49] float mid=hEdist->Integral(980,1020)
root [50] float hi=hEdist->Integral(1021,2000)
root [51] mid/(low+mid+hi)
(double)9.52039148017112202e-01
```

One of the questions I had in working through all this was that if I fit the distribution above and get a width, how is that width (which is projected onto the x axis) related to the 2D width. Doing the Mathematica integral below it appears there is no difference in the width.

$$\text{In}[30]= \int_{-\infty}^{+\infty} \text{Exp}\left[-\frac{x^2 + y^2}{2 * s1^2}\right] dy$$

$$\text{Out}[30]= \text{If}\left[\text{Re}[s1^2] > 0, \frac{e^{-\frac{x^2}{2s1^2}} \sqrt{2 \pi}}{\sqrt{\frac{1}{s1^2}}}, \text{Integrate}\left[e^{-\frac{x^2+y^2}{2s1^2}}, \{y, -\infty, \infty\}, \text{Assumptions} \rightarrow \text{Re}[s1^2] \leq 0\right]\right]$$

Integral of a 2D gaussian over one dimension leaves you with a gaussian of the same width.

Jerry Gilfoyle's Enotebook page 321 - First Look at Bose-Einstein Correlations at the EIC. (gpg)

[Modified Wed Aug 11 22:32:28 2010 (GMT) gpg]

The measurement of Bose-Einstein Correlations (BEC) at the EIC could enable us to extract the source size of an excited color string and possibly gain information on the tension in the string. One way to study BECs is to look at correlations in the relative momentum between two identical particles. The correlation coefficient is defined as the ratio of the relative momentum spectrum between, say, two π^0 's divided by the same spectrum with any correlations removed. Experimentally, this 'no-correlations' spectrum has to be generated with some care, but here we will be using simulation where we can easily turn the correlations on and off. These correlations have been observed at ZEUS (and other places) and we use some of that work to guide our studies here. For this study we looked at two-pion momentum correlations using the Pythia event generator. It turns out that Pythia version 6.4 comes with the capability to turn on these correlations.

To start the first figure below shows the correlation function measured at ZEUS from ep events. The data sample used consisted mostly (about 80%) of pion tracks.

Fig 1. Plot from Zeus, arXiv:hep-ex/0311030v2 and Phys.Lett.B583:231-246,2004.

To test the BEC part of Pythia we used the ZEUS kinematics (see Figure 2) and the average value of the BEC parameters from the ZEUS paper. We extracted the relative momentum from all pairs of pions in each event and generated histograms with BEC on and off (left-hand side of Figure 2). We used the Gaussian BEC simulation and the parameters shown in Figure 2. To get the correlation function we simply divided the BEC-on histogram by the BEC-off one. We did not run the simulation for very long, but we see a clear correlation at low relative momentum with a shape qualitatively similar to the ZEUS results. The pythia simulation is broader (crosses zero at $\Delta p = 1 \text{ GeV}/c$ instead of $0.4 \text{ GeV}/c$ for the ZEUS data), but we this is a very simple analysis at this stage.

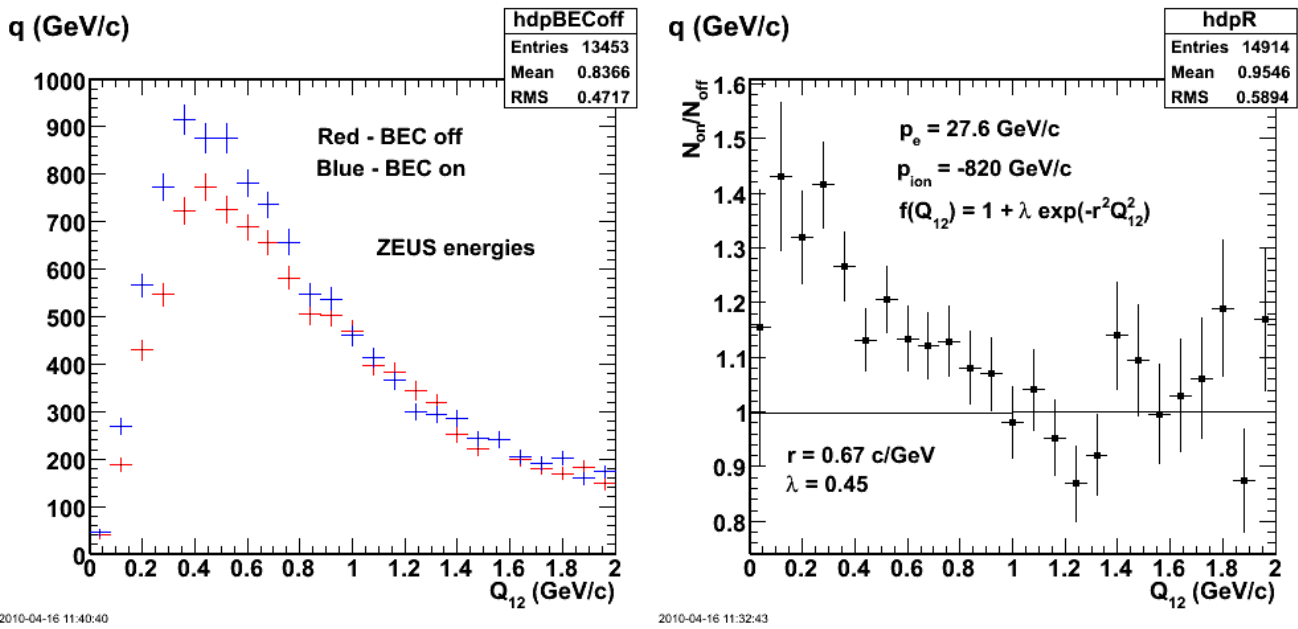

Fig 2. Comparison of spectra from pythia BEC simulation at ZEUS energies (left panel) and correlation function for ZEUS energies (right panel).

Next, we took the same parameters and used possible EIC momenta for the electron and ion beams and did the same simulation. The results are shown in Figure 3. The correlation at small relative momentum has largely disappeared. This case is a much lower energies than the ZEUS so perhaps there is simply not enough energy to produce the large number of mesons needed to see this effect. This is a bit surprising since Hayk has observed a significant correlation among pion pairs in the EG2 data set at even lower energy transfers (See Figure 4).

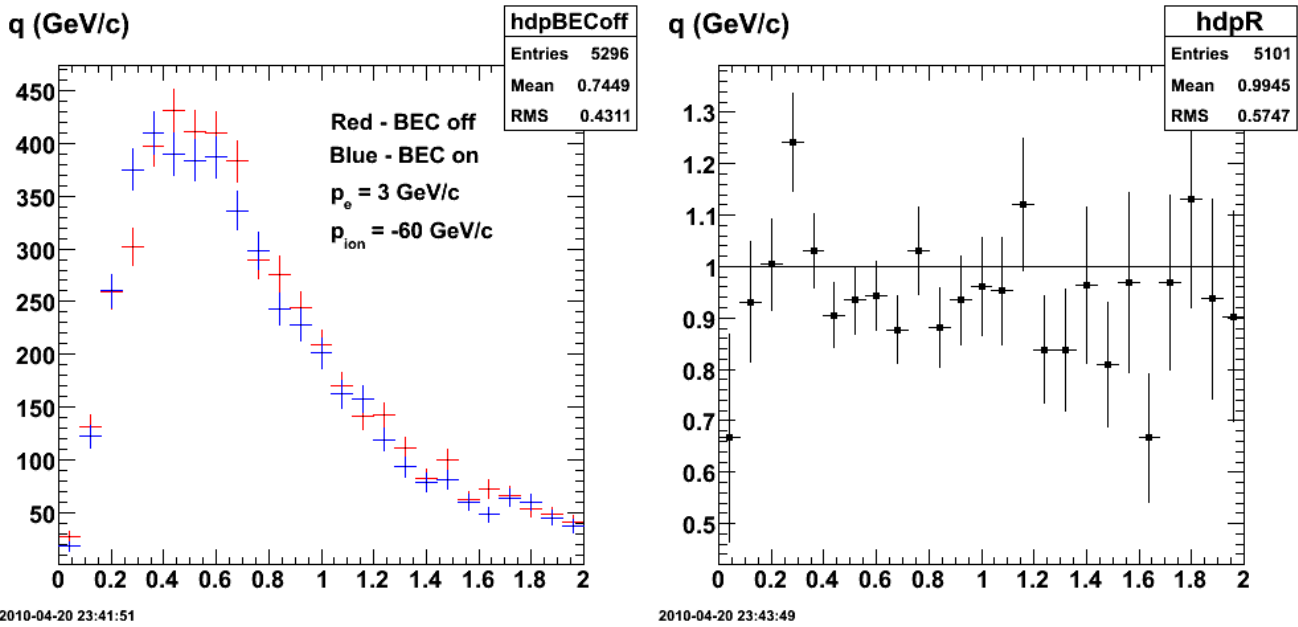

Fig 3. Comparison of spectra from pythia BEC simulation at EIC energies (left panel) and correlation function for EIC energies (right panel). Pythia parameters are the same as in Figure 2 except the incoming momenta.

Correlations from $\pi^+\pi^+$ were extracted from the CLAS6 EG2 data and show a significant positive correlation at low relative momentum, but are hampered by the close-track inefficiencies in CLAS6.

I take a first look at the Q_2 dependence of pythia and there is an anomalous peak at $Q_2=0$. It is not from $Q_2 < 0$ events and the plot below shows there are many events with very small Q_2 . Q_2 here was calculated from the square of the magnitude of the transferred photon which is particle 4 in the pythia event record.

2010-05-06 14:59:01

Fig 10. Log-Log plot of Q_2 distribution showing the large peak at very low (but > 0) Q_2 . It is not clear where this is from, but remove it from the data. Horizontal axis is Q_2 (GeV^2).

Take the parameters from Figs 22-22a where we tried to reproduce Hayk's CLAS6 results (with limited success, we get the value of the correlation at Q12=0, but can't reproduce the width) and apply them at EIC energies. The higher energy amplifies the maximum value of the correlation, but has little effect on the width of the distribution.

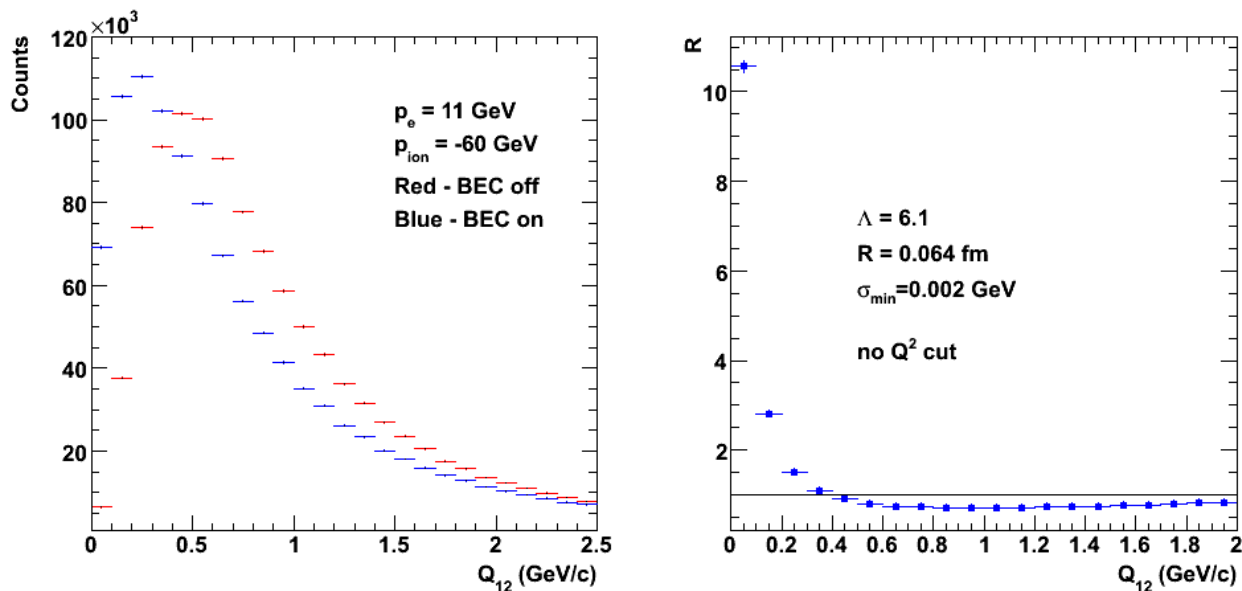

Fig 27. Use pythia parameters from figs 22-22a for CLAS6 kinematics and run them at EIC kinematics. Used the exponential form of the parameterization.

Click [here](#) to view the object (ROOT macro) you uploaded.

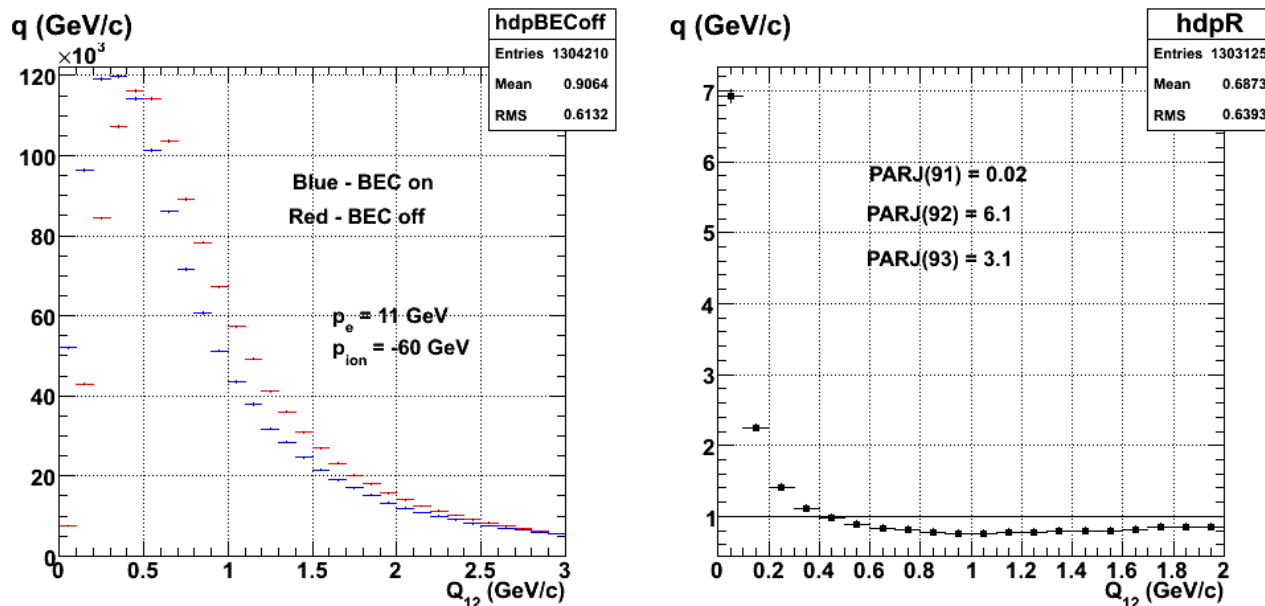

Fig 28. Study the effect of increasing PARJ(91) back to the default value. The maximum correlation at $S_{12}=0$ decreases, but the rest of the shape stays much the same.

Jerry Gilfoyle's Enotebook page 322 - eod: checking effect of radiative corrections (gpg)

[Modified Tue Apr 27 18:59:35 2010 (GMT) gpg]

I expect that the radiative corrections to the asymmetry will be small because we are looking at the ratio of cross sections and the measured asymmetry is only about $\pm 5\%$. Results are below for runs with EXCLURAD. I found that changing the size of the σ_{LT} had absolutely no effect out to the number of significant digits used by EXCLURAD. I then changed the other response functions to test for any effect and did see small changes.

$E = 2.558 \text{ GeV}$, $W = 2.218 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, $\nu_{\text{cut}} = 0.310 \text{ GeV}$, 5% LT

Jerry Gilfoyle's Enotebook page 323 - Radiative Corrections for Fifth Structure Function Analysis (gpg)

[Modified Wed May 12 02:44:36 2010 (GMT) gpg]

I have been operating under the assumption that the radiative corrections (RCs) to the helicity asymmetry will be small like the GMn corrections and I would treat them as a small addition to the systematic uncertainty. It appears that is not the case. I have noticed for some time that when I arbitrarily change the size of the R_LTp response function in the deep.f code used in my d(e,e'p)n version of EXCLURAD there is no change in the RC. After much anguish, trials and tribulations this week and discussions with Andrei I now realize the effect could be significant. Some results are shown in the table below. The columns are e1 (ignore), W, Q2, cscm_input(i), phicm_input(i), silar(1)/sibar(1), silar(2)/sibar(2), (silar(2)/sibar(2))/(silar(1)/sibar(1)) (see exclurad.f for definitions).

```

The last column shows the ratio of the RC for the polarized part of the cross section to the RC for the unpolarized part. At forward angles the difference is less than 1%, but grows to 14% near 90 degrees. In the analysis we will have to average this ratio over the missing momentum bin and then divided the measured asymmetry by that bin-averaged ratio. See entry [154](#) for the connection between missing momentum and θ_{pq} .

The code is available in the tar archive at the end of this paragraph. This version includes calculations for both the polarized and unpolarized RCs though care must be taken with the polarized cross sections. The response functions from WVO's deep code for the imaginary part of the L_T interference (R_LTp) are about 15-16 orders of magnitude smaller than the longitudinal and transverse response functions (R_L and R_T). It appears this befuddles the integration routines and they never converge in a reasonable amount of time. You can turn off the polarized calculation by setting ipolmax=1 in exclurad.f. I found it helpful to merely set the value of R_LTp to something large and calculate the RC from that. This is actually ok since there is only one term here in the polarized RC. The RC depends only on the shape, i.e. the angular distribution of the cross section and not it's size. I found you could multiply R_LTp by any reasonable value and there was no change in the RC. Andrei agreed this was appropriate behavior. We see the same thing with the unpolarized RC when we set all the response functions to zero except one. In other words set all the response functions to zero except R_T. Calculate the RC and then multiply R_T by 10 and you get the same answer for the RC.

Click [here](#) to view the object (tar archive of EXCLURAD with polarized RC.) you uploaded.

Below is my list of observations on EXCLURAD.

1. R_LTp is many orders of magnitude smaller in the van order model so it has no effect.
2. When I include R_LTp in the calculation it looks like the integration breaks in qqtll and never converges.
3. Resetting sig_LTp to something large like 0.5*sig_T enables the integration to converge.
4. Changes to the size of sig_LTp STILL have no effect on the radiative correction.
5. Even using sig_LTp = 100.0*sig_T*cos(thetac) and sig_LTp = 0.1*sig_T*cos(thetac) has no effect.
6. The radcor is still sensitive to changes in the other response functions.
7. The sig_T test: (1) turn off all the response functions except sig_T and get radcor. (2) Multiply sig_T by something large like 100. (3) There should be no change in the RC. This IS seen.
8. Use just sig_T again, but now turn on a factor of cos(thetac). RC should change and IT DOES.
9. It looks like the unpolarized correction is independent of size, but not cos(thetac). How do we add those up??? We don't!! There are separate RCs for the polarized and unpolarized cases. For the fifth structure function analysis we are taking the ratio of the polarized cross section to the unpolarized. We will take the ratio of the polarized RC to the unpolarized RC and divide this into the asymmetry ALTp.

The plot below shows the results for W = 2.0 GeV, Q2 = 0.5 GeV which corresponds to quasielastic scattering of d(e,e'p)n. The ratio is the polarized, full-calculation RC divided by the same calculation for the unpolarized cross section.

OOPPSS! The plot below is wrong due to an indexing problem. I was using the leading log approximation in the RC calculation which makes no distinction between polarized and unpolarized cross sections so the plot should have been flat with a constant value of one. When I went back and checked the original input file that was true. See Fig 2 for a revised (and correct) calculation.

Fig 1. Ratio of polarized to unpolarized radiative corrections for $W = 2.0, Q^2 = 0.5 \text{ GeV}^2$ $d(e, e' p) n$ (QE kinematics). NOTE: The label on the vertical axis is wrong!

Click [here](#) to view the object (Mathematica notebook for above result.) you uploaded.

Fix the indexing problem that messed up Fig 1 and get the result below. The RC for ALTp now appears to be large especially at small angles where the precision is high!!! I hope this correction doesn't screw things up!!

Fig 2. Ratio of polarized to unpolarized radiative corrections for $W = 2.0, Q^2 = 0.5 \text{ GeV}^2$ $d(e, e' p) n$ (QE kinematics). This plot replaces Fig 1.

Jerry Gilfoyle's Enotebook page 324 - Problems with Mathematica Interpolation (gpg)

[Modified Tue May 11 20:36:48 2010 (GMT) gpg]

In going from Mathematica 7.0 on my laptop and at Richmond to v6 at JLab, the 3D interpolation doesn't seem to work right any more. The first plot shows a combined ListPointPlot3D showing the points in the array plus the ListPlot3D. The points all appear to sit on the surface.

Fig 1. Overlay of the original array of points plotted with ListPointPlot and the surface made with ListPlot.

Now I create a set of points with the x and y meanings reversed in order to use the interpolation function in Mathematica. The first element of each ordered triplet is treated as the 'x' value which is fixed and the 'y' value varies. I use that array in the interpolation function and it appears to work except it looks like the $\cos(\theta)$ sequence is reversed! A BUG???! See RCsystUncertainty13b.nb.

Fig 2. Overlay of points with x and y values reversed and plotted with the surface produced by interpolating that array!!

Next, I multiply the $\cos(\theta)$ value by -1 and I get something that is qualitatively like the points, but shows significant differences.

Fig 3. Overlay of REVERSED $\cos\theta$ points with interpolated surface based on UNREVERSED points!!

The plots I generated recently at home or at school yesterday look ok. See RCsystUncertainty13.nb.

Jerry Gilfoyle's Enotebook page 325 - Draft of tutorial stuff for CSW (gpg)

[Modified Mon May 24 00:15:20 2010 (GMT) gpg]

Below is a draft of the material I will put on the CLAS12 software wiki.

Some sample commands:

1. How to change geometry using the database.

- Go to `/home/clas/gemc/production/database_io/clas12/geo/ec`. If you don't have this try `svn checkout https://clas12svn.jlab.org/repos/trunk/clas12/gemc/production`.
- Edit `ec_build.pl`.
- Run `go_table`.
- Run `gemc` with the following command. The input file `modified2.gcard` is available here.

```
gemc -gcard=modified2.gcard -DATABASE=user_geometry -BEAM_P="e-, 8.0*GeV, 10.0*deg, 0*deg"
```

2. Effects of turning magnetic field on and off. The input file `modified2.gcard` is available here.

a. Run `gemc` with the following command.

```
gemc -gcard=modified2.gcard -BEAM_P="e-, 8.0*GeV, 10.0*deg, 0*deg"
```

b. Now turn the field off by adding the `-NO_FIELD` option.

```
gemc -gcard=modified2.gcard -BEAM_P="e-, 8.0*GeV, 10.0*deg, 0*deg" -NO_FIELD=all
```

3. Effect of changing electron momentum and spread. The input file `modified2.gcard` is available here.

Vary the values for options `-BEAM_P`, `-SPREAD_P`, `-SPREAD_V`.

```
gemc -gcard=modified2.gcard -BEAM_P="e-, 8.0*GeV, 20*deg, 0*deg" -SPREAD_P="0.2*GeV, 2*deg, 18*deg" -SPREAD_V="(0.1, 0.1, 2.5)cm"
```

4. Effects of changing the luminosity. The input file `modified2.gcard` is available here.

Vary the values for options `-LUMI_P`, `-LUMI_V`, and `-LUMI_EVENT`.

```
gemc -gcard=modified2.gcard -LUMI_P="e-, 11*GeV, 0, 0" -LUMI_V="(0, 0, -10)cm" -LUMI_EVENT="2000, 124*ns, 2*ns"
```

5. Using a different event generator with the LUND format. The input file `modified2.gcard` is available here.

```
gemc -gcard=modified2.gcard -BEAM_P="e-, 8.0*GeV, 20*deg, 0*deg" -SPREAD_P="0.2*GeV, 2*deg, 18*deg" -INPUT_GEN_FILE="LUND,ep_event.lund"
```

Jerry Gilfoyle's Enotebook page 326 - Tests of eod exclurad calculations (gpg)

[Modified Thu Jun 3 21:25:06 2010 (GMT) gpg]

The results below are for QE kinematics for $Q^2 = 0.5 \text{ GeV}^2$, $E_{\text{beam}} = 2.6 \text{ GeV}$.

Comparison of unpolarized RC_{best} calculated by taking the ratio of $\sigma_{\text{best}}^{\text{unpol}}$ with $\sigma_{\text{Born}}^{\text{unpol}}$ with the result directly from exclurad. First plot is calculated from the individual cross sections and the second is from the direct output of exclurad. They agree with one another.

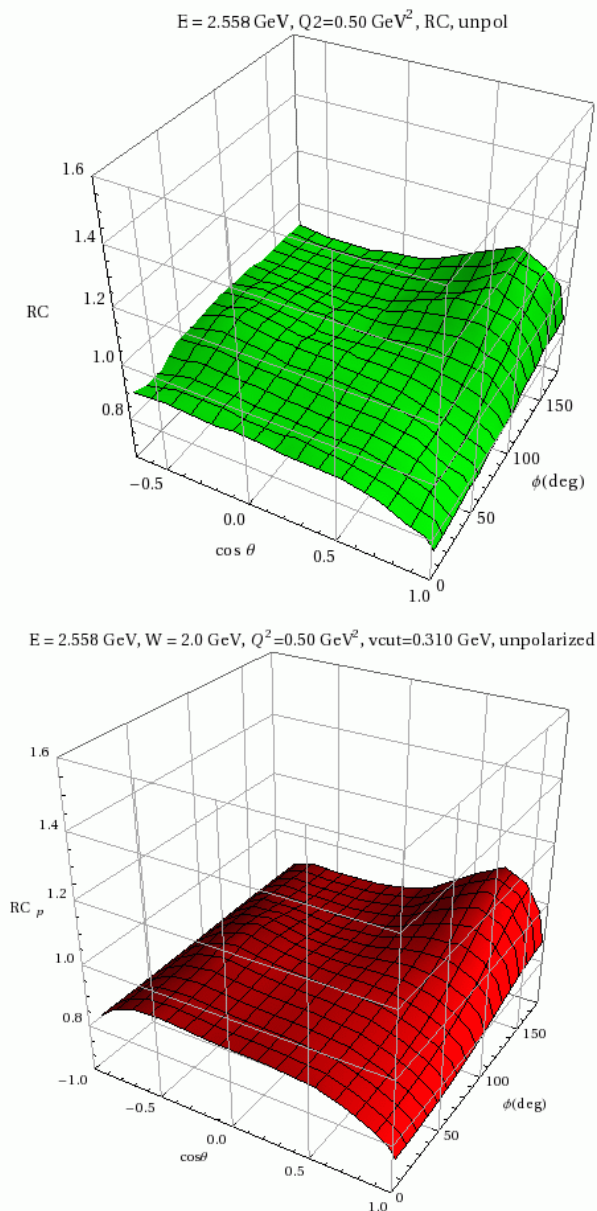

Fig 1. Comparison of RC directly from EXCLURAD and calculated from the cross sections for the unpolarized, 'best' calculation.

Comparison of unpolarized RC_{II} calculated by taking the ratio of σ_{II}^{pol} with σ_{Born}^{pol} with the result directly from excludrad. First plot is calculated from the individual cross sections and the second is from the direct output of excludrad. The plots are mislabeled as unpolarized. They agree with each other.

Fig 2. Same as Fig 1 except now with unpolarized, leading-log calculation.

Comparison of polarized $RC_{||}$ calculated by taking the ratio of $\sigma_{||}^{pol}$ with σ_{Born}^{pol} with the result directly from exclud. First plot is calculated from the individual cross sections and the second is from the direct output of exclud.

Plot from RCsystemUncertainty14.nb showing the polarized leading log RC. It agrees with the previous plot.

Fig 3. Same as Figs 1-2 now with polarized, leading-log calculations.

Jerry Gilfoyle's Enotebook page 327 - Behavior of RC calculations (gpg)

[Modified Tue Jun 8 00:05:39 2010 (GMT) gpg 1]

The problem here is that the ratio of unpolarized to polarized RCs varies enough that it will effect the extraction of ALTp. See Fig 2 in entry 323 and the right-hand panel of Fig 1. At Andrei's suggestion, I am looking at the behavior of the cross section calculations used in EXCLURAD. The large magnitudes in the ratio of the polarized to unpolarized RCs is worrisome so we are trying to understand where the effect comes from. The plots below show the cross section of the polarized cross section from DEEP (Figs 1-2), for the unpolarized cross section and the Born cross section.

Looking over the figures, the polarized cross section is dropping rapidly in the region at forward polar angles ($\cos\theta_{pq} > \sim 1$) and large azimuthal angles ($\phi_{pq} \sim 180$ deg). See Fig 1a. In contrast, the unpolarized cross section is rising rather comparatively gently in that region. See Fig 3. Perhaps this difference creates the large (20%) disparity in the ratio of the RC corrections seen in entry 323 and Fig 1b.

After discussions with Andrei, our conclusion is the following.

1. For $\cos\theta_{pq} \sim 1$, we will effectively average over the full ϕ_{pq} range. We typically have the first bin at $p_m < 0.05$ GeV/c which corresponds to $\theta_{pq} < 6$ deg and $\cos\theta_{pq} > 0.994$. See entry on Sabine's formulas relating θ_{pq} and p_m .
2. The asymmetry in that first bin (and several after) is close to zero so any change will be small.
3. The effect of the large ratio for $\cos\theta_{pq} \sim 1$ and $\phi_{pq} \sim 180$ will be reduced in the averaging and will multiply a small number for the asymmetry. The overall effect on our results will likely be vanishingly small. For the 2.6r ALTp results in entry 248, $ALTp = 0.0008 \pm 0.0015$. The calculation of the average effect of the RC_{pol}/RC_{unpol} dependence in that first bin (i.e. for $\cos\theta_{pq} = 0.99$) is 1.02 (see [here](#)) which changes ALTp by a negligible amount.

Jerry Gilfoyle's Enotebook page 329 - Production plots of RC calculations (gpg)

[Modified Mon Feb 21 17:37:53 2011 (GMT) gpg 1]

The plots below are from the new cluster and have more points to improve the resolution of the RC calculation. Plots show the wire plot and the surface plot for polarized and unpolarized RCs and the ratio. All are for the full calculation. Compare Figure 1 with Fig 1b of entry 327.

$E = 2.56 \text{ GeV}$, $W = 2.0 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, $v_{\text{cut}} = 0.310 \text{ GeV}$, polarized

Fig 1. Point plot of polarized RC.

$E = 2.56 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, polarized

Surface plot polarized RC, full calculation.

$E = 2.558 \text{ GeV}$, $W = 2.0 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, $v_{\text{cut}} = 0.310 \text{ GeV}$, unpolarized

Fig 2. Point plot of unpolarized RC, full calculation.

$E = 2.558 \text{ GeV}$, $W = 2.0 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, unpolarized

Surface plot unpolarized RC, full calculation.

Fig 3. Ratio of polarized to unpolarized RCp.

Click [here](#) to view the object (Mathematica notebook) you uploaded.

Add more points to these kinematics and plot.

$E = 2.56 \text{ GeV}, W = 2.0 \text{ GeV}, Q^2 = 0.50 \text{ GeV}^2, v_{\text{cut}} = 0.310 \text{ GeV}, \text{polarized}$

Fig 4. Point plot of polarized RC.

$E = 2.56 \text{ GeV}, Q^2 = 0.50 \text{ GeV}^2, \text{polarized}$

Surface plot polarized RC, full calculation.

$E = 2.558 \text{ GeV}$, $W = 2.0 \text{ GeV}$, $Q^2 = 0.50 \text{ GeV}^2$, $v_{\text{cut}} = 0.310 \text{ GeV}$, unpolarized

Fig 5. Point plot of unpolarized RC, full calculation.

Jerry Gilfoyle's Enotebook page 330 - Testing the new form of the EC geometry. (gpg)

[Modified Fri Aug 6 17:33:18 2010 (GMT) gpg]

Below is a test of the ec_build.pl script used for generating the EC geometry for gemc. The new version takes a more sensible approach to the geometry by casting it a form which generates the geant4 inputs for G4Trap directly instead of using the Ralph Minehart version from CLAS6. The table below compares the output from the old ec_build.pl (left column) with the new version (right column) for a few of the layers.

Old version of ec_build.pl

```

Click [here](#) to view the object (Old version of ec_build.pl (left-hand columns)) you uploaded.

Click [here](#) to view the object (New version (called ecgeo.pl) of calculations for ec_build.pl (right-hand column).) you uploaded.

The results above are fine, but we have not optimized the representation of the EC geometry in ec_build.pl. We start doing that now. The plot below and the associated version of ec_build.pl are our starting point.

Fig 1. Starting configuration of EC with old geometry.

Click [here](#) to view the object (ec_build.pl) you uploaded.

Now fire a geantino track at the vertex of the scintillator layer 1 closest to the beamline. Plot below was generated with the following command.

```
gmc -gcard=modified.gcard -DATABASE=user_geometry -N=2 -BEAM_P="geantino, 8*GeV, 4*deg, 0.0*deg" -NO_FIELD=all
```

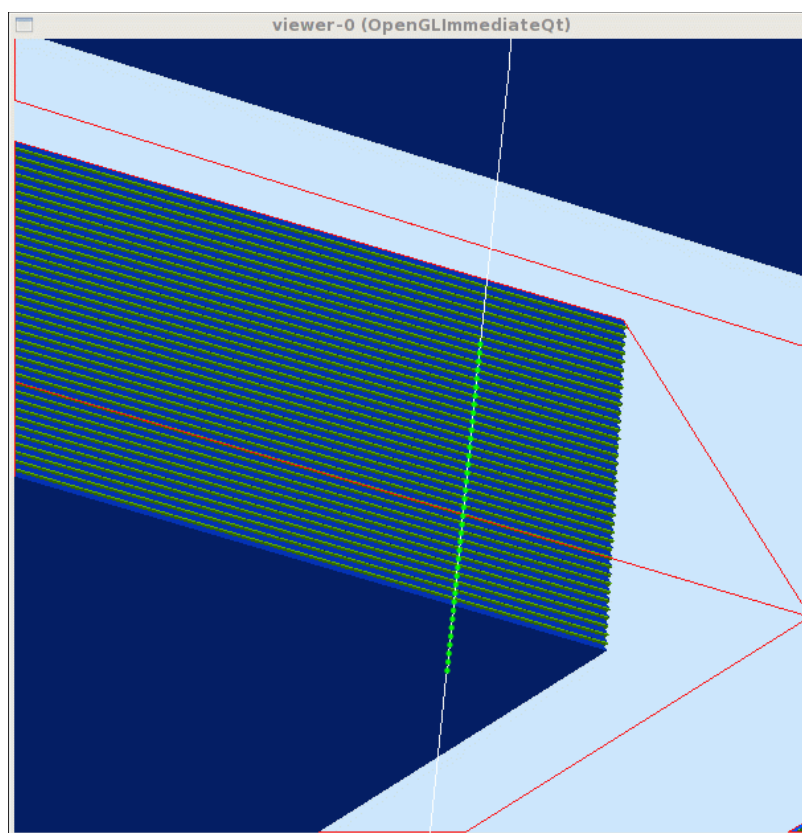

Fig 1. Geantino track fired at the beam-side vertex of layer 1 with theta = 4 deg.

Plot below was generated with the following command.

```
genc -gcard=modified.gcard -DATABASE=user_geometry -N=2 -BEAM_P="geantino, 8*GeV, 3.99999*deg, 0.0*deg" -NO_FIELD=all
```

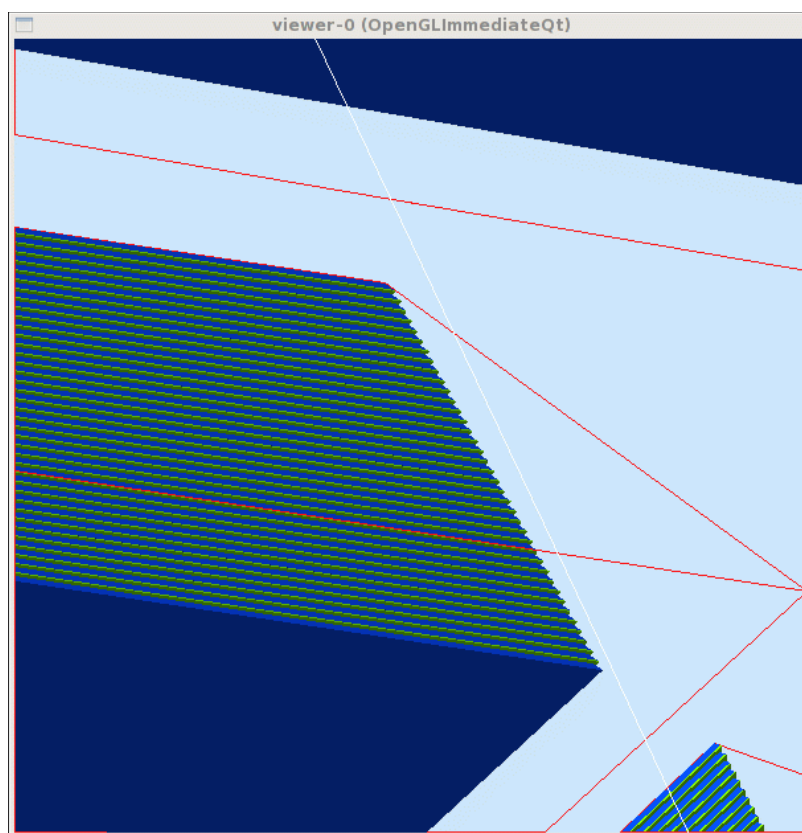

Fig 2. Geantino track fired at the beam-side vertex of layer 1 with $\theta = 3.99999$ deg.

Now set the polar angle at the minimum value of the angle in layer 1 (at the beam-side vertex). Geantinos were generated with the following command.

```
genc -gcard=modified.gcard -DATABASE=user_geometry -N=2 -BEAM_P="geantino, 8*GeV, 3.6886*deg, 0.0*deg" -NO_FIELD=all
```

Fig 3. Geantino track fired at the beam-side vertex of layer 1 with theta = 3.6886 deg.

It looks like we can't specify angles with greater than 1 deg of precision for the internal event generator. Try using the LUND format input files to get the precise angles. At the expected minimum of θ we get lots of hits.

```

1 1. 1. 1. 0 -1 0.0 0.0 0.8804 9.037 4.816
1 -1. 1 11 0 0 0.3860 0.0 5.9876 6.0000 0.0005 0.0000 0.0000 0.0000

```

Fig 4. Fired an electron at $\theta = 3.689$ deg and it looks like it hits the corner.

AT $\theta = 3.5$ de we get hits. At $\theta = 2.5$ deg no hits. At $\theta = 3.0$, the track appears to just graze the first layer. See next plot.

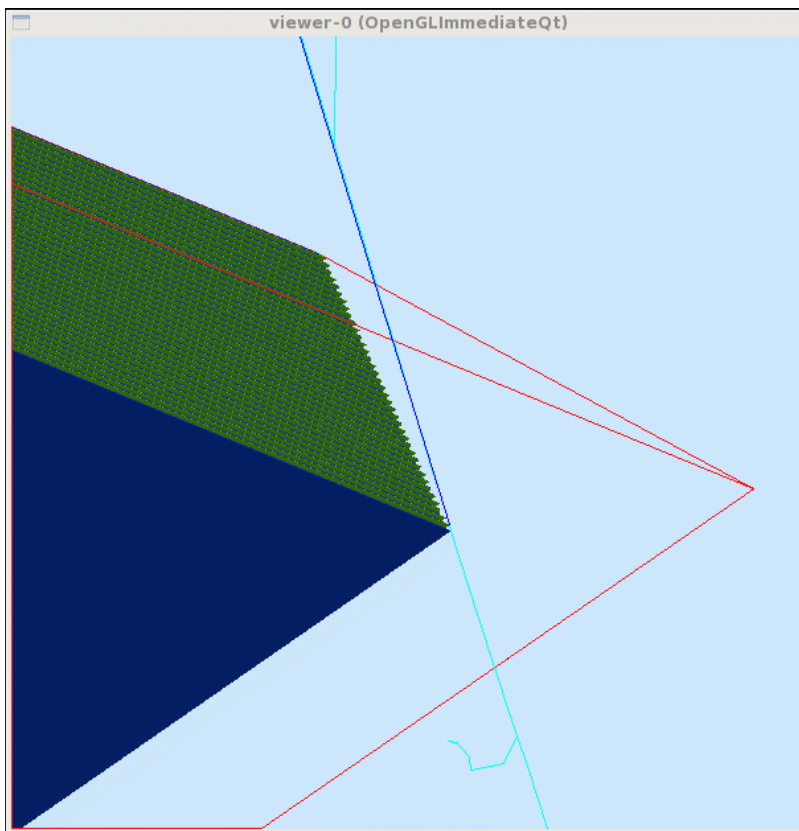

Fig 5. Fired an electron at $\theta = 3.0$ deg and it looks like it missed the edge.

Appears to hit at $\theta = 3.25$ deg.

```
1 1. 1. 0 -1 0.0 0.0 0.8804 9.037 4.816

```

Fig 4. Fired an electron at $\theta = 3.25$ deg and it looks like it hits the corner.

Jerry Gilfoyle's Enotebook page 331 - Track Reconstruction with Socrat (gpg)

[Modified Tue Aug 3 14:44:27 2010 (GMT) gpg]

Plots generated trying to debug electron reconstruction problem with Socrat and recent gemc sims.

F1. Residuals for new gemc run. Labelled wrong. Its the new file. Units are meters.

Click [here](#) to view the object (Root macro) you uploaded.

F2. Let all the hits in. Units are meters.

Click [here](#) to view the object () you uploaded.

F3. Old file with good reconstruction. Units are meters.

Click [here](#) to view the object (Root macro) you uploaded.

F4. Old file, excluded hits. Units are meters.

Click [here](#) to view the object (Root macro) you uploaded.

Comparing Figs 3-4 above there are channels where the 'all hits' analysis has fewer events than the 'excluded hits' analysis which makes no sense. Check this by extracting the hits from a single analysis run. The plot below shows this and it looks correct. The problem in Figs 3-4 was likely pilot error as usual.

F5. Direct comparison of residual with all hits and excluded hits from same analysis run. Units are meters.

Click [here](#) to view the object (Root macro) you uploaded.

Results from internal event generator in Socrat.

F6. Momentum distribution for reconstructed tracks. $p = 6 \text{ GeV}/c$, $\theta = 21 \text{ deg}$, $\phi = 230 \text{ deg}$.

F14. ϕ distribution for reconstructed tracks with increased value on left-right ambiguity cut.

Click [here](#) to view the object (Root macro) you uploaded.

Set `-USE_PHYSICSL=gemc` in the `gemc` command and things look good!!!!!!!!!!!!!!!!!!!!!! Plot below shows results for reconstructed momentum, θ , and ϕ as shown above. The number of throws was 20000 so it looks like Socrat tried to make some noise into tracks maybe. The widths are significantly larger than the widths using the internal Socrat event generator, but these can likely be cleaned up by getting rid of the outliers in the distributions below. Used the following command to generate the events.

```
gemc -gcard=modified2.gcard -N=20000 -BEAM_P="e-, 6.0*GeV, 21.0*deg, 230.0*deg" -OUTPUT="evio, results.ev" -PRINT_EVENT=50 -USE_QT=0 -USE_PHYSICSL=gemc
```

F15. Distribution of reconstructed p , θ , and φ for events generated with gemc and analyzed with C++ Socrat.

Jerry Gilfoyle's Enotebook page 333 - Testing effect of shape of BEC (gpg)

[Modified Wed Sep 22 16:07:44 2010 (GMT) gpg]

The following are attempts to see any effect associated with different longitudinal and transverse shapes of the BEC source. For Fig 1 the following parameters were used. There is little difference between this and the previous version that had no source asymmetry as shown in Fig 2 and entry [332](#).

The results below are ALL for EIC kinematics with $p_e=11$ GeV and $p_{ion}=-60$ GeV. Ignore the labelling on the plots.

c turn on BEC parameters

```
if (BECswitch .eq. '2') then
  print *, 'Setting Parameters for BEC.'

Fig 11. Try and get a narrow distribution like the results above when I used the Lund model, but using the user inputs.

Click [here](#) to view the object (Root macro) you uploaded.

A bit of a summary: Turning on the independent fragmentation scheme in pythia (and turning off the Lund model) creates very broad R distributions that do not look like the data from the LHC, ZEUS, or EG2. The independent fragmentation scheme does allow you to have an asymmetric momentum distribution (transverse versus longitudinal) which is, I believe, something we would like to observe at the EIC. It would be good to tune the independent fragmentation parameters to resemble the Lund model results for symmetric fragmentation, but I am having no success at doing that.

Another try at getting a narrow R distribution with independent fragmentation.

c turn on BEC parameters

  print *, 'No BEC.'
endif

```

2010-09-24 16:13:40

Fig 6. Correlation function at EIC kinematics with ZEUS BEC parameters.

Click [here](#) to view the object (Root macro) you uploaded.

Now go to CLAS6 kinematics. The BEC paramters are the same as the code in the previous two examples so I won't reproduce them here. The correlation has gone away in contradiction of Hayk's EG2 results. Is this a pythia problem? supposedly pythia uses a soft process (fragmentation) to produce the correlations which should be independent of Q2.

2010-09-24 16:28:03

Fig 7. All hints of a correlation disappear at CLAS6 energies which is inconsistent with Hayk's results.

Click [here](#) to view the object (Root macro) you uploaded.

Set the FRAME option to FIXT in PYINIT to check pythia for running with a stationary target. In the calculations above I used 3MOM which corresponds to collider frame and set the momenta of the ion to zero for stationary targets. The results (shown below) are the same; no correlation.

2010-10-01 13:02:12

Fig 8. Run pythia with FIXT option in PYINIT and get the same result.

Jerry Gilfoyle's Enotebook page 335 - Study of transverse and longitudinal source size in Pythia (gpg)

[Modified Tue Oct 12 21:31:24 2010 (GMT) gpg]

Here we study the transverse/longitudinal properties of the BECs by boosting to the Longitudinal Center of Mass System (see eic3.f for the code). We use EIC kinematics ($p_e=11$ GeV, $p_{ion}=-60$ GeV) and the following input.

```
c turn on BEC parameters
  if (BECswitch .eq. '2') then
    print *, 'Setting Parameters for BEC.'
    MSTJ(51) = 0
    MSTJ(52) = 3
    MSTJ(53) = 0
    MSTJ(54) = 2
    MSTJ(55) = 0
    MSTJ(56) = 0
    MSTJ(57) = 1

    lambda=0.9
    R=0.9

    PARJ(91) = 0.02
    PARJ(92) = lambda
    PARJ(93) = 0.2/R
  c   PARJ(94) = 0.0
  c   PARJ(95) = 0.02
  c   PARJ(96) = 0.02

  else
    print *, 'No BEC.'
  endif
```

2010-10-04 18:49:07
Fig 1. Run pythia with MSTP(51)=0 which turns off the BEC to check that things are ok.

Click [here](#) to view the object (Root macro) you uploaded.

Now turn on the BEC correlations and we get a pretty plot. The width of the longitudinal correlation is larger than the transverse one which has a larger incoherency.

```
c turn on BEC parameters
  if (BECswitch .eq. '2') then
    print *, 'Setting Parameters for BEC.'
    MSTJ(51) = 1
    MSTJ(52) = 3
    MSTJ(53) = 0
    MSTJ(54) = 2
    MSTJ(55) = 0
    MSTJ(56) = 0
    MSTJ(57) = 1

    lambda=0.9
    R=0.9
```

```

PARJ(91) = 0.02
PARJ(92) = lambda
PARJ(93) = 0.2/R
c PARJ(94) = 0.0
c PARJ(95) = 0.02
c PARJ(96) = 0.02

```

```

else
  print *, 'No BEC.'
endif

```

2010-10-04 19:22:21

Fig 2. Now turn on the BEC and there is a spectacular difference between the transverses and longitudinal parts.

Same as above except make PARJ(22)=10.0 which is ten times bigger than the default value.

Fig 5. Drastically increase the asymmetry factor and there is still very little effect.

I am worried that I have not interpreted the definition of the LCMS correctly. It may be that the z-axis in the LCMS is along the direction of the 3-momentum transfer while I had assumed before it was along the jet axis which for a two-pion event would be the direction of the sum of the individual pion momenta. Below I have modified eic3.f to use this different definition and get drastically different looking correlations functions. These don't look like anything in the literature so I am guessing my first interpretation of the LCMS is the correct one.

2010-10-06 14:34:40

Jerry Gilfoyle's Enotebook page 336 - Study of TOF NDE (gpg)

[Modified Fri Nov 19 20:55:19 2010 (GMT) gpg]

Take a renewed look at the TOF NDE for Mark Moog's DNP poster for fall, 2010. First look at the results are shown below. Clearly there are problems with the analysis in Socrat. This problem was seen before in entry [245](#).

Fig 1. Momentum resolution in Socrat.

Click [here](#) to view the object (Root macro) you uploaded.

I moved all of the moog software for Socrat over to my area and changed the location of the torus field map in Read_TorusFM.h to /home/gilfoyle/nde/moog/run and ran a gemc output file on my directory on the master. It worked!!! The only hint from Socrat there was a problem was that I did not see the progress outputs as the file was read. No other warnings. That sucks. The resolution plot is below.

Fig 2. Momentum resolution using the magnetic field file in my run area.

Click [here](#) to view the object (Root macro) you uploaded.

Make massive changes to MM code to get it to reproduce the analysis I did from August, 2009. I abandoned Trees and inserted some histograms into Socrat.cxx. It seems to work.

Jerry Gilfoyle's Enotebook page 337 - Elastic Kinematics (gpg)

[Modified Wed Aug 24 19:50:31 2011 (GMT) gpg]

An entry with some plots and formulas that I keep having to look up for elastic kinematics for the gmn project. The first two plots show the elastic electron energy as a function of electron angle θ for $E = 11$ GeV. The *Mathematica* notebook is at the link after figure 2.

Figure 1. Electron energy as a function of electron scattering angle for 11 GeV beam.

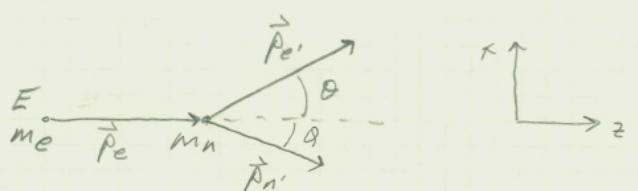

Figure 2. Sum of the electron (θ) and neutron (φ) scattering angles as a function of θ .

Click [here](#) to view the object (*Mathematica* notebook for calculations above.) you uploaded.

Click [here](#) to view the object (PDF version of scanned pages below.) you uploaded. Derivation of the formulas used in the calculations above is below.

1

$p_e = (E, \vec{p}_e) = (E, 0, 0, E)$
 $p_n = (E_n, \vec{p}_n) = (m_n, 0, 0, 0)$
 $\vec{p}_{e'} = (E', \vec{p}_{e'}) = (E', p_e \sin \theta, 0, p_e \cos \theta)$
 $\vec{p}_{n'} = (E_n', \vec{p}_{n'}) = (E_n', p_n' \sin \phi, 0, p_n' \cos \phi)$

for the electron $p_e = E, p_{e'} = E'$

$$p_e + p_n = p_{e'} + p_{n'} \quad (1)$$

in elastic scattering

$$p^2 = E^2 - p^2 = m^2 \quad \text{for both particles}$$

$$(p_e + p_n)^2 = (p_{e'} + p_{n'})^2$$

$$p_e^2 + 2p_e \cdot p_n + p_n^2 = p_{e'}^2 + 2p_{e'} \cdot p_{n'} + p_{n'}^2$$

$$m_e^2 + 2p_e \cdot p_n + m_n^2 = m_e^2 + 2p_{e'} \cdot p_{n'} + m_n^2$$

$$p_e \cdot p_n = p_{e'} \cdot p_{n'}$$

Set E' in terms of E and θ .

$$\text{use } p_e + p_n = p_{e'} + p_{n'}$$

$$\therefore p_{n'} = p_e + p_n - p_{e'}$$

$$p_e \cdot p_n = p_{e'} \cdot p_{n'}$$

$$= p_{e'} \cdot (p_e + p_n - p_{e'})$$

$$= p_{e'} \cdot p_e + p_{e'} \cdot p_n - p_{e'}^2$$

use the explicit forms of the 4-vectors on page 1.

$$p_e \cdot p_n = (E, 0, 0, E) \cdot (m_n, 0, 0, 0) = E m_n$$

$$p_{e'} \cdot p_{e'} = (E', E' \sin \theta, 0, E' \cos \theta) \cdot (E', 0, 0, E') \\ = E' E' - E' E' \cos \theta$$

$$p_{e'} \cdot p_n = (E', E' \sin \theta, 0, E' \cos \theta) \cdot (m_n, 0, 0, 0) \\ = E' m_n$$

$$\therefore E m_n = E E' (1 - \cos \theta) + E' m_n - \cancel{E'^2}$$

$$E m_n = E' (E (1 - \cos \theta) + m_n)$$

$$E' = \frac{E m_n}{m_n + E (1 - \cos \theta)}$$

$$= \frac{E m_n}{m_n \left(1 + \frac{E}{m_n} (1 - \cos \theta) \right)}$$

$$1 - \cos \theta = 2 \sin^2 \frac{\theta}{2}$$

$$E' = \frac{E}{1 + \frac{2E}{m_A} \sin^2 \frac{\theta}{2}}$$

For a given θ , what is ϕ ?

Match components of the momenta

$$E = p_{e1} \cos \theta + p_{n1} \cos \phi$$

$$p_{n1} \cos \phi = E - p_{e1} \cos \theta$$

$$0 = p_{e1} \sin \theta - p_{n1} \sin \phi$$

$$p_{n1} \sin \phi = p_{e1} \sin \theta$$

$$\therefore \frac{p_{n1} \sin \phi}{p_{n1} \cos \phi} = \frac{E' \sin \theta}{E - E' \cos \theta}$$

$$\tan \phi = \frac{E' \sin \theta}{E - E' \cos \theta}$$

$$\phi = \tan^{-1} \left(\frac{E' \sin \theta}{E - E' \cos \theta} \right)$$

Page 3.

Now get the neutron/proton momentum in terms of the beam energy E and the neutron/proton angle.

4

Let p_n and q
 from p'

$$P_e P_n = P_e \cdot P_n'$$

get P_n in terms of E and q

$$P_e + P_n = P_e' + P_n'$$

$$P_e' = P_e + P_n - P_n'$$

$\therefore P_e P_n = P_n' (P_e + P_n - P_n')$

$$= P_e P_n' + P_n P_n' - P_n'^2$$

$$P_e P_n = (E, 0, 0, E) \cdot (m_n, 0, 0, 0) = E m_n$$

$$P_e P_n' = (E, 0, 0, E) \cdot (E_n, -P_n' \sin \theta, 0, P_n' \cos \theta)$$

$$= E E_n - E P_n' \cos \theta$$

$$P_n P_n' = (m_n, 0, 0, 0) \cdot (E_n, -P_n' \sin \theta, 0, P_n' \cos \theta)$$

$$= m_n E_n$$

$$E m_n = E E_n - E P_n' \cos \theta + m_n E_n - m_n^2$$

$$E n^2 = p_n^2 + m_n^2$$

$$E m_n = \sqrt{p_n^2 + m_n^2} E' - p_n E \cos \theta +$$

$$m_n \sqrt{p_n^2 + m_n^2} - m_n^2$$

$$Em_n = \sqrt{p_n^2 + m_n^2} (E + m_n) - p_n E \cos \theta - m_n^2$$

$$Em_n + m_n^2 + p_n E \cos \theta = \sqrt{p_n^2 + m_n^2} (E + m_n)$$

$$\frac{m_n (E + m_n)}{E + m_n} + \frac{p_n E \cos \theta}{E + m_n} = \sqrt{p_n^2 + m_n^2}$$

$$m_n + \frac{p_n E \cos \theta}{E + m_n} = \sqrt{p_n^2 + m_n^2}$$

$$\sqrt{p_n^2 + m_n^2} = m_n + \frac{p_n E \cos \theta}{E + m_n}$$

$$\cancel{p_n^2} + \cancel{m_n^2} = \cancel{m_n^2} + \frac{p_n^2 E^2 \cos^2 \theta}{(E + m_n)^2} + \frac{2 m_n p_n E \cos \theta}{E + m_n}$$

$$p_n^2 \left(1 - \frac{\cos^2 \theta}{(1 + m_n/E)^2} \right) +$$

$$p_n \left(\frac{2 m_n \cos \theta}{1 + m_n/E} \right) = 0$$

$$p_n \left[p_n \left(1 - \frac{\cos^2 \theta}{(1 + m_n/E)^2} \right) + \frac{2 m_n \cos \theta}{1 + m_n/E} \right] = 0$$

$$\therefore p_n = 0 \quad \text{or}$$

$$p_n \left(1 - \frac{\cos^2 \theta}{(1 + m_n/E)^2} \right) + \frac{2 m_n \cos \theta}{1 + m_n/E} = 0$$

$$p_n = - \frac{2 m_n \cos \theta}{1 + m_n/E} \cdot \frac{1}{1 - \frac{\cos^2 \theta}{(1 + m_n/E)^2}}$$

$$\begin{aligned} p_n &= - \frac{2m_n \cos \theta}{1 + m_n/E} \frac{(1 + m_n/E)^2}{(1 + m_n/E)^2 - \cos^2 \theta} \\ &= - \frac{2m_n \cos \theta (1 + m_n/E)}{1 + \frac{m_n^2}{E^2} + \frac{2m_n}{E} - \cos^2 \theta} \end{aligned}$$

Jerry Gilfoyle's Enotebook page 338 - NDE γ distribution (gpg)

[Modified Fri Dec 24 18:11:12 2010 (GMT) gpg]

Study the behavior of the NDE γ distribution. We typically require $\gamma < 10$ deg between the direction of the found neutron (determined from the electron information and the assumption of QE scattering from the neutron) to call a hit a QE neutron. It appears the neutrons all have zero deposited energy while the electron has a deposited energy of around 10 MeV.

Fig 1. γ distribution for $E_{\text{dep}} < 8$ MeV.

Fig 2. Effect of requiring the the TOF hit to be in the same sector as the found neutron.

Fig 4. Comparison of γ distribution with E_{dep} and sector cuts with MC selection of known neutrons.

Click [here](#) to view the object (Root macro) you uploaded.

Better version of things now using the proper E_{dep} cut. For limited statistics the next fig shows the total number of hits that survive the E_{dep} cut (there are lots and lots of $E_{dep}=0$ hits that get eliminated) in black and there is a peak likely due to electron hits. It's a peak at about the angle of the electron relative to the neutron hits. The red curve shows the γ distribution requiring the E_{dep} cut and the hit has to be in the sector of the neutron predicted from QE scattering of the neutron. The blue curve shows the γ distribution requiring E_{dep} and using the MC information to require the hit be a neutron. We are overestimating the number of neutrons in the sample!??

Fig 10. Add electron tracking results and generated information to neutronTracking tree and check things. What are the spikes? events with crap??

Spikes were caused by me setting the number of events in Socrat to a test value of 1000 when there were only 200 events in the gemc output file.

2010-12-07 22:19:39

Fig 11. Comparison of angular distributions of electrons generated from the MC (black) and reconstructed by Socrat (red). There is an obvious problem at small angles and there are angle bins where the efficiency is greater than one.

Click [here](#) to view the object (Root macro) you uploaded.

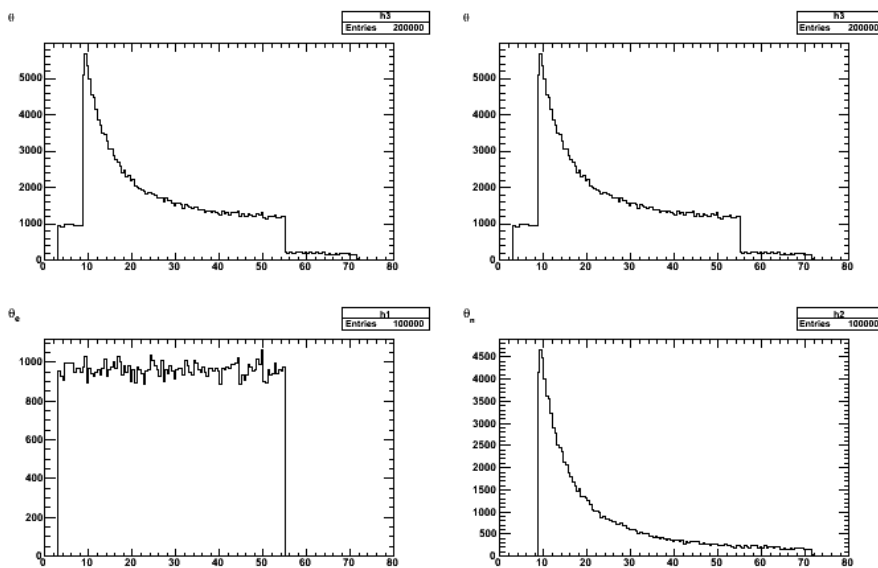

Fig. 12 Generated input to gemc. The low angle cut on the neutron angle is due to the upper limit on the electron angle.

Click [here](#) to view the object () you uploaded.

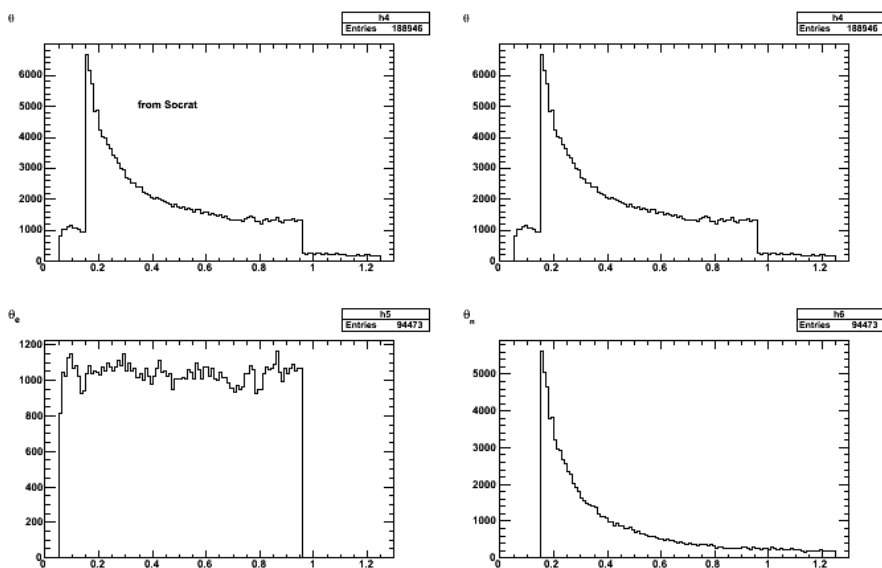

Fig 12. Generated input from Socrat.

The weird peak in the electron angular distribution at forward angles seems to be an artifact of Socrat. See the upper-right plot of p_e vs θ_e in Fig 13 where there is a large blob of events at small angles with momentum greater than the beam momentum. It also appears the minimum electron angle is larger than I thought; out at about 11 deg.

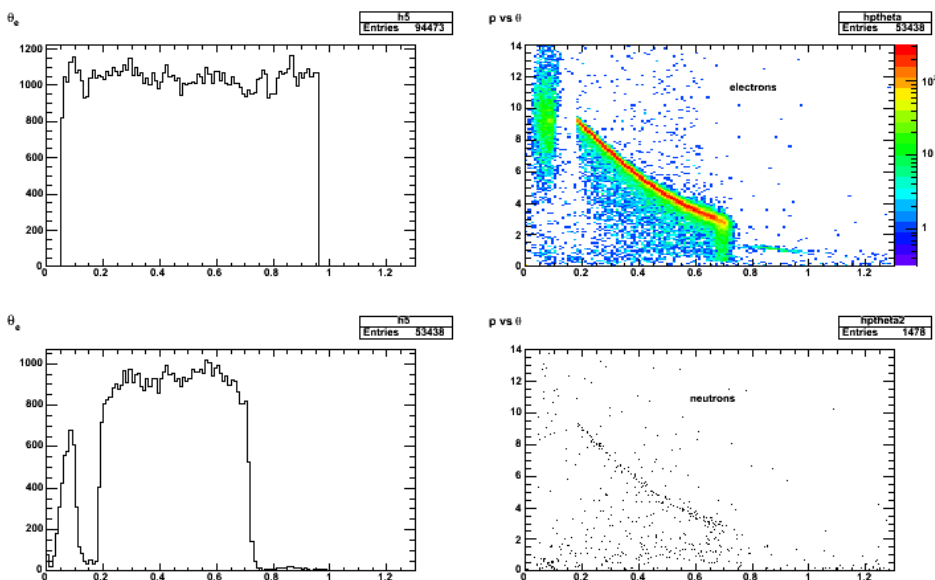

Fig 13. Continuing study of weirdness in Socrat.

Click [here](#) to view the object (ROOT macro) you uploaded.

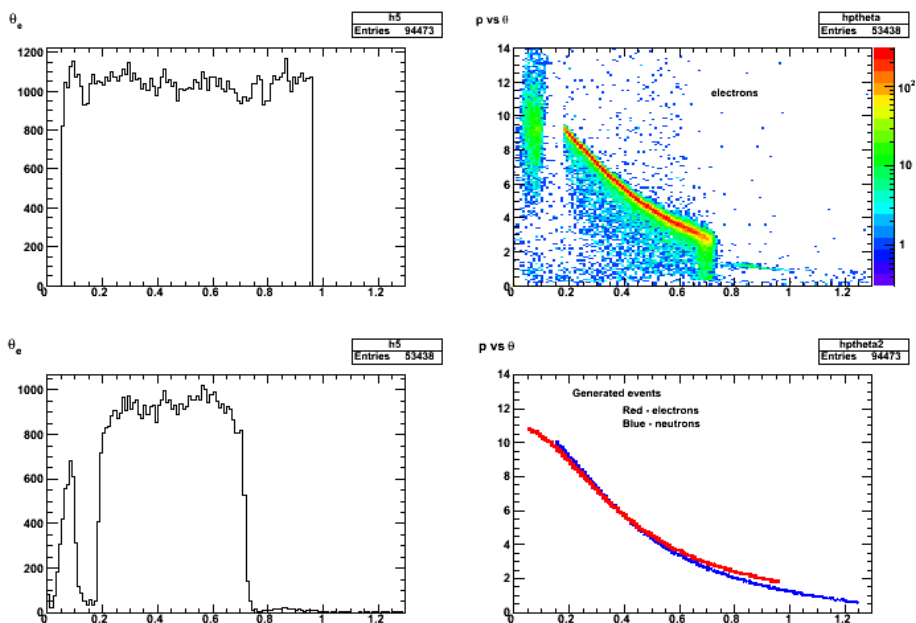

Fig 15. Check the generated momentum vs. θ dists.

Click [here](#) to view the object (ROOT macro) you uploaded.

The upper-left panel in Fig 16. shows the generated electron momentum vs. θ_e for reconstructed electrons with $\theta_e < 0.15$ rad. The anomalous peak appears to be coming from those very-forward events.

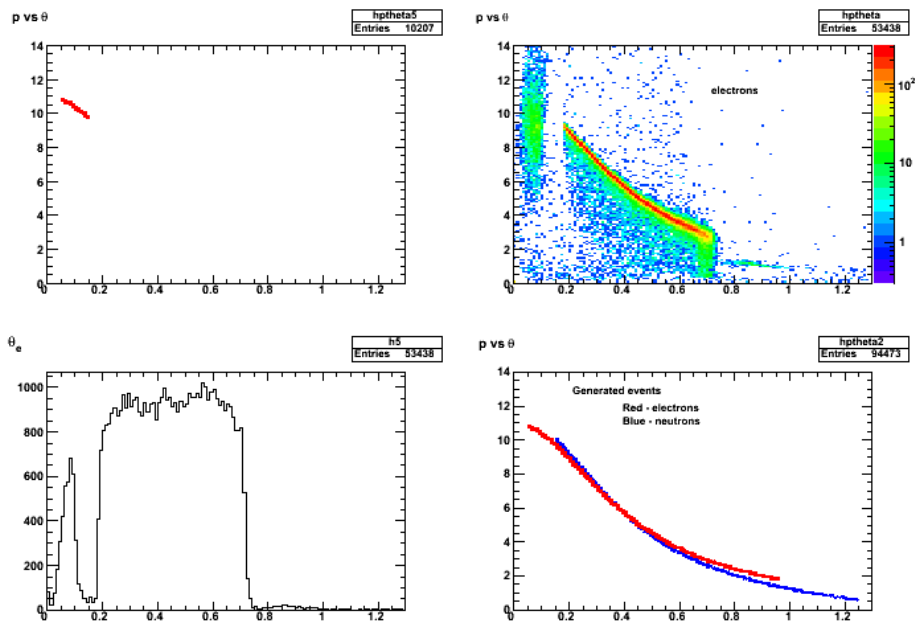

Fig 16.

Click [here](#) to view the object (ROOT macro) you uploaded.

Effect of requiring hits in the TOFs gets rid of the forward-angle wacko electron hits. I still don't understand why the 'good' events only go down to $\theta_e = 0.2$ rad (11 deg)? This is presumably for the 'standard' torus polarity which is electrons inbending.

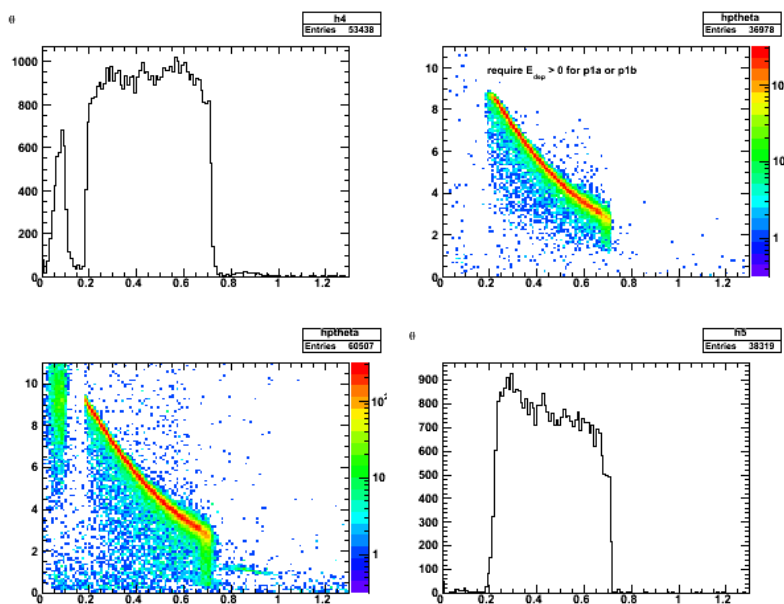

Fig 17. Effect of requiring hits in TOF p1a or p1b panels.

Click [here](#) to view the object (ROOT macro) you uploaded.

Try the reversed polarity to see what happens then. Forgot to put in plots, but saw the screwy, small-angle peak was not as well separated from the higher-angle group. These may be saying that reversed field will smear out the small-angle stuff at this stage of the reconstruction.

Put some cuts on the energy deposited in the OTOF1a and OTOF1b and things are cleaned up substantially at the cost of losing about 90% of the events. It also shows the minimum electron angle is about 11 deg which is much larger than expected. Turning off the $g_id=11$ requirement brings in a few more events (total = 3151 vs. 2813).

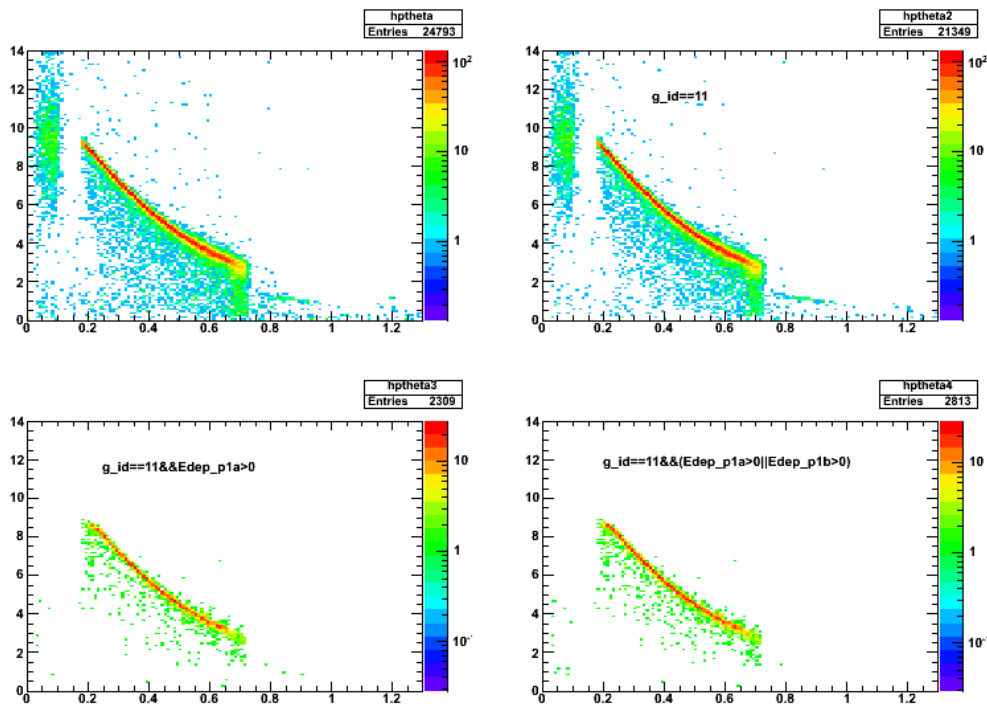

Fig 18. Comparison of momentum vs. θ_e for various cuts.

Click [here](#) to view the object (ROOT macro) you uploaded.

Now include the thrown electrons in the upper, left panel. It still looks like we are cutting off electrons below 11 deg which corresponds to a minimum $Q^2=3.7$ GeV². That is still ok for the GMn overlaps with the CLAS6 measurement.

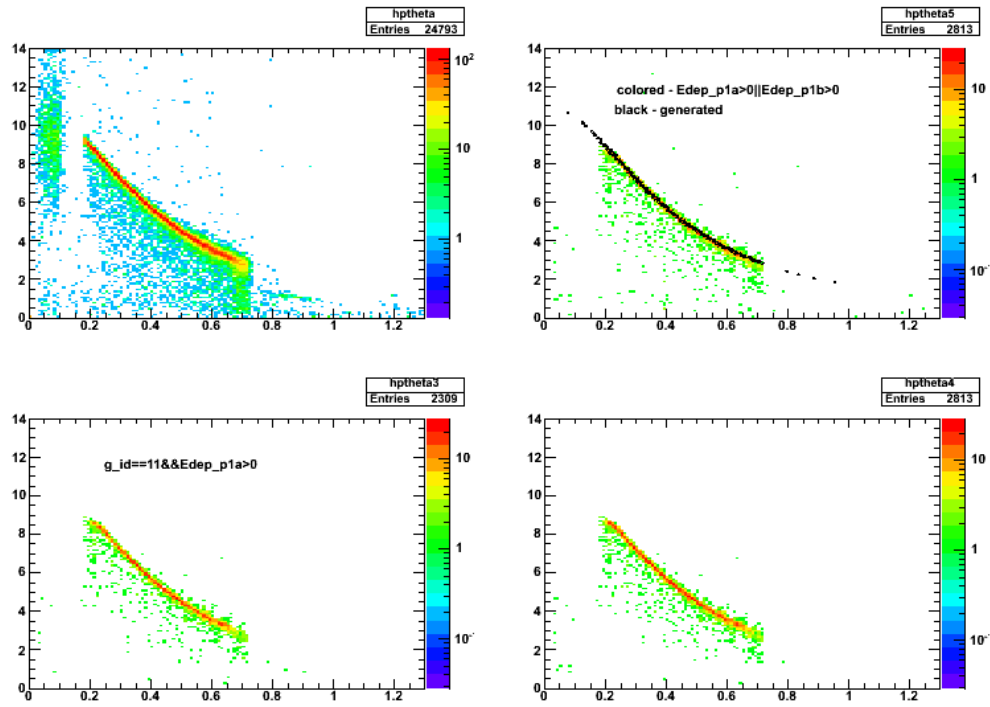

Fig 19. Same comparison as in fig 18 with the thrown electrons included in the upper left panel.

Jerry Gilfoyle's Enotebook page 340 - Precision Tests for BEC (gpg)

[Modified Thu Dec 16 16:28:46 2010 (GMT) gpg]

I want to get some idea of the ability to distinguish between correlation functions with different values of the source size r . The uncertainty on the fits in the ZEUS ep paper are very small; about 1-3%. I have taken some of the correlation functions from the talk and fitted them with the ZEUS function and get larger uncertainties with lower statistics in the fits. The left-hand panel below is the correlation function ($\pi^+\pi^+$) without separation into LT parts. The right-hand panel is the correlation function for the longitudinal part and $r=0.73$ in the inputs.

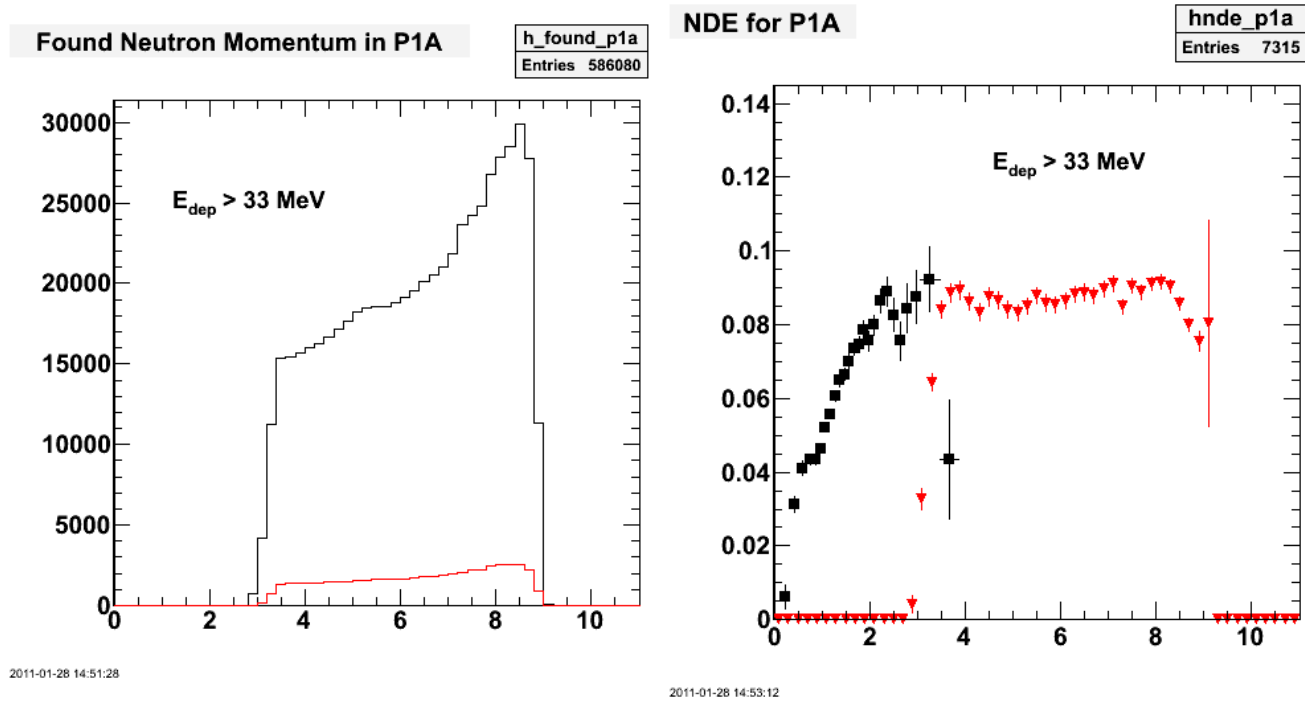

Fig 1. Comparison of two different correlation functions and their fits.

Jerry Gilfoyle's Enotebook page 343 - RC correction for ALTp (gpg)

[Modified Fri Mar 25 20:42:20 2011 (GMT) gpg]

Starting collecting results for RC correction to ALTp. Since the correction appears to be significant and different and varies with \hat{I}_T for the polarized and unpolarized parts of the cross section, then I have to put in the correction on each separately. (1) The first step is to generate the 2D surfaces (functions of $\cos\hat{I}_T$ and \hat{I}_T) for polarized and unpolarized at many different Q^2 values. The first plot below shows the surfaces for polarized RC correction for $Q^2=0.2$ GeV² (red) and $Q^2=0.5$ GeV² (blue). Mathematica notebooks for separate Q^2 calculations are below fig 1.

Fig 1. Comparison of polarized RC at $Q^2=0.2$ GeV² (red) and $Q^2=0.5$ GeV² (blue).

Fig 10. Effect of full calculation with improved handling of events outside the kinematic range of the RC calculation.

Jerry Gilfoyle's Enotebook page 344 - Low p_m asymmetry for 2.6r (gpg)

[Modified Fri Mar 4 03:25:36 2011 (GMT) gpg]

The plot below shows ALTp at small p_m where it should go to zero.Fig 1. Low p_m dist for 2.6r.Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 345 - Comparison of 2.6r old and new (gpg)

[Modified Wed Apr 20 15:15:56 2011 (GMT) gpg]

I want to compare the default version of the asymmetries with my current analysis for 2.6r just to make sure things are consistent. Plot below shows this comparison. Things are very close for the high-stats, low-pm results and there is a small difference at large pm.

Fig 1. 2.6r comparison.

Click [here](#) to view the object (Root macro) you uploaded.

The parameters used in user_eod5.h are listed below.

```
//
// important parameters of the analysis.
//
Double_t Me = 0.000511;
Double_t Mp = 0.938272;
Double_t Mn = 0.93956533;
Double_t Mpi = 0.1396;
Double_t Md = 1.875;
Double_t Ebeam = 2.55814;
Double_t deuterium_upstream = -11.5, deuterium_downstream = -8.0; // default
//Double_t neutron_mm2_lo = 0.84, neutron_mm2_hi = 0.92; // old default values up to 8/12/09
//Double_t neutron_mm2_lo = 0.83, neutron_mm2_hi = 0.91; // new default values up to 8/31/09
//Double_t neutron_mm2_lo = 0.75, neutron_mm2_hi = 0.97; // new default values
Double_t neutron_mm2_lo = 0.83, neutron_mm2_hi = 0.91; // new default values for 2.6r
//Double_t neutron_mm2_lo = 0.83, neutron_mm2_hi = 0.91; // new default values for 2.6n
//Double_t neutron_mm2_lo = 0.84, neutron_mm2_hi = 0.92; // test 9/11/09
```

```
Double_t W_QE_lo=0.91, W_QE_hi=0.99; // default values
```

From other entries in the elog (275, 276, and 279), the lower limit on the W cut should be 0.89 instead of 0.91. Entry 270 has the 2.6n archive of the analysis code. Rerun the analysis with Wmin=0.89 GeV and things change significantly. Sigh!! I can't believe I got this wrong.

Fig 2. Add the result of the corrected lower limit on W.

Fig 5. ALtp for today.

Click [here](#) to view the object (Root macro) you uploaded.

I was not drawing the lachniet sampling fraction cut lines properly in figs 1-4 above. That was corrected in the plots below. It clearly seems that I need different limits on the cut as drawn in the figure. The red lines are the old limits from jeff and the brown ones are the new ones.

test.

Jerry Gilfoyle's Enotebook page 347 - Proton Mass cut (gpg)

[Modified Tue Mar 22 12:19:01 2011 (GMT) gpg]

I am reexamining the proton mass cut. The current default values are

```
Double_t mass_p_lo=0.90, mass_p_hi=0.996; // default 10/20/09
```

which appear to be tight in Fig 1. (red lines) so I will make them larger to capture more statistics (black lines).

2011-03-21 16:08:12

Fig 2. Proton mass cut. See entry 200 for more.

Click [here](#) to view the object (Root macro) you uploaded.

Fig 2. To set the context; unweighted missing momentum spectra for +/- helicities.

Click [here](#) to view the object (Root macro) you uploaded.

2011-03-21 17:29:03

Fig 3. Effect on ALTp of turning on proton mass cut. It weakens the asymmetry which is the opposite of previous results.

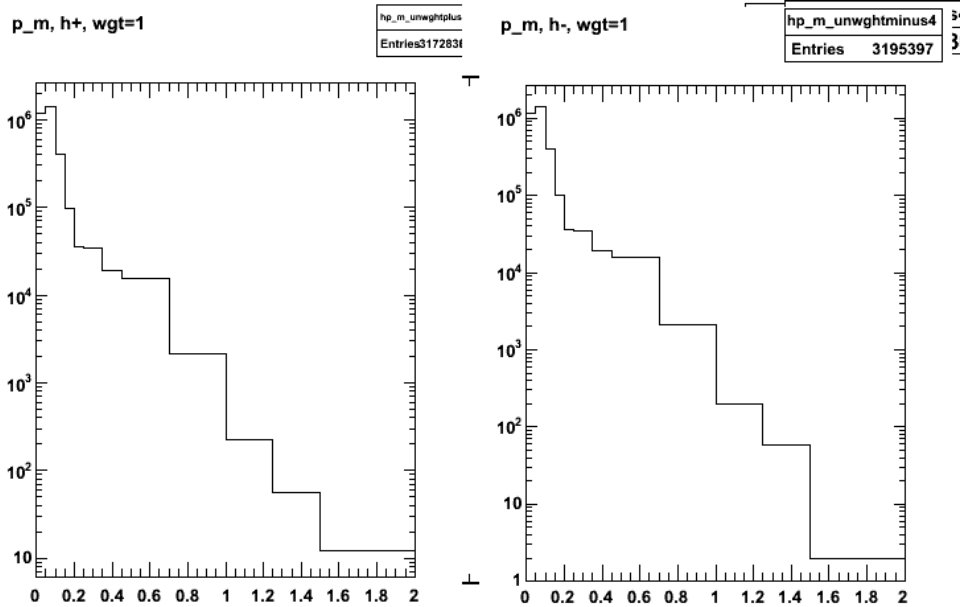

Fig 4. Comparison of unweighted p_m spectra. Notice that the number of events went UP??!! How can that be. Rerun the analysis with just the m_p cut removed.

Click [here](#) to view the object (Root macro) you uploaded.

Rerun the exact same analysis code with m_p cut commented out and things look sane. The likely problem was that I was using the old sampling fraction cut. ALTp dip does get a tiny bit deeper.

2011-03-21 18:02:20

Fig 5. Comparison of ALP with (red) and without (blue) proton mass cut.

Fig 6. Comparison of unweighted p_m spectra. These now look reasonable in comparison with the same spectra with the proton mass cut turned on in fig 4.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 348 - Setting up DOE2000 elog (gpg)

[Modified Wed May 25 20:03:41 2011 (GMT) gpg]

Installing DOE2000 (ENOTE).

1. Installed XAMPP (xampp-linux-1.7.4.tar) from <http://www.apachefriends.org/en/xampp-linux.html> and extracted it to /opt
2. Downloaded enote from http://www.csm.ornl.gov/~geist/enote/zips/enote1_12.tar and untar it in /opt/lampp/htdocs.
3. Placed the two .pl files from enote1.12/cgi-bin in /opt/lampp/cgi-bin.

```
root-gpg4:cgi-bin> cp ../htdocs/enote1.12/cgi-bin/enote112.pl .
root-gpg4:cgi-bin> cp ../htdocs/enote1.12/cgi-bin/enotelib.pl .
root-gpg4:cgi-bin> pwd
/opt/lampp/cgi-bin
```

4. Placed the rest of the files from enote1.12 into /opt/lampp/htdocs

```
root-gpg4:enote1.12> pwd
/opt/lampp/htdocs/enote1.12
root-gpg4:enote1.12> dir
total 28
drwxr-sr-x. 2 8149 gopher 4096 May 23 22:14 cgi-bin/
-rw-r--r--. 1 8149 gopher 3339 Feb 3 2004 enote1_12_readme.txt
drwxr-sr-x. 4 8149 gopher 4096 Feb 3 2004 html/
-rw-r--r--. 1 8149 gopher 12669 Feb 3 2004 install.txt
```

5. Added the ExecCGI option to the cgi-bin directory in /opt/lampp/etc/httpd.conf

```
#
# "/opt/lampp/cgi-bin" should be changed to whatever your ScriptAliased
# CGI directory exists, if you have that configured.
#
    AllowOverride None
#   Options None <---- comment this out.
    Options ExecCGI <---- add this.
    Order allow,deny
    Allow from all
```

6. Allowed access from all in the file /opt/lampp/etc/extra/httpd-xampp.conf

```
#
# New XAMPP security concept
#
    Order deny,allow
# default is to have the following 4 lines uncommented and not have the Allow from all line.
#   Deny from all
#   Allow from :::1 127.0.0.0/8 \
#           fc00:::7 10.0.0.0/8 172.16.0.0/12 192.168.0.0/16 \
#           fe80:::10 169.254.0.0/16
#   Allow from all <---- this is the change.
    ErrorDocument 403 /error/XAMPP_FORBIDDEN.html.var
```

7. Changed the variables in /opt/lampp/cgi-bin/enote112.pl to reflect the paths of the required files.

```
---
$main::notebook{'gpg'} = {(
  'dir' => '/opt/lampp/htdocs/enote1.12/html/gpg/',
  'title' => "Jerry Gilfoyle's Notebook",
});

# Example of how to specify additional notebooks
#$main::notebook{'data'} = {(
#  'dir' => 'c:/httpd/root/enote1.12/html/instrument/',
#  'title' => "Raw Instrument Data Notebook"
# });

$main::nb = 'gpg';
---
```

```
#####
#
# Section 3: General configuration flags and variables
#
#####

# Set to 1 if flock() exists (server is Unix), to 0 otherwise (Windows/Mac).
$main::flock = 0;

# Directory of the shared notebook library routines 'enotelib.pl'.
$main::libdir = '/opt/lampp/cgi-bin';      <--- change this
```

8. Comment out the following (lines 79-90) in the lampp config file (/opt/lampp/lampp) to NOT check for 32-bit compatibility.

```
# XAMPP is currently 32 bit only
#case `uname -m` in
#   * 64)
#     if /opt/lampp/bin/php -v > /dev/null 2>&1
#     then
#       :
#     else
#       $de && echo "XAMPP gibt es zur Zeit nur als 32-Bit Applikation. Bitte verwende eine 32-Bit Kompatibilitaetsbibliothek fuer Dein System."
#       $de || echo "XAMPP is currently only available as 32 bit application. Please use a 32 bit compatibility library for your system."
#       exit
#     fi
#   ;;
#esac
```

9. Make a symbolic link in /opt/lampp/htdocs to the enote112.pl script in /opt/lampp/cgi-bin/ so perl finds the right script.

```
root-gpg4:htdocs> ln -s /opt/lampp/cgi-bin/enote112.pl enote112.pl
root-gpg4:htdocs> pwd
/opt/lampp/htdocs
root-gpg4:htdocs> dir
total 800
drwxr-sr-x. 4 8149 gopher 4096 Feb 3 2004 enote1.12/
lrwxrwxrwx. 1 root root 30 May 23 23:14 enote112.pl -> /opt/lampp/cgi-bin/enote112.pl
-rw-r--r--. 1 root root 768000 May 23 22:14 enote1.12.tar
-rw-r--r--. 1 root root 30894 May 11 2007 favicon.ico
-rw-r--r--. 1 root root 256 Feb 5 2009 index.php
drwxr-xr-x. 2 nobody root 4096 Jul 15 2009 webalizer/
drwxr-xr-x. 7 root root 4096 Jan 7 03:48 xampp/
```

10. Get selinux set up properly.

```
yum install selinux-policy.noarch
```

```
yum install setools
```

```
setsebool -P allow_execstack on
```

takes a while.

11. Start up the daemon.

```
/opt/lampp/lampp start
```

```
root-gpg4:htdocs> /opt/lampp/lampp start
Starting XAMPP for Linux 1.7.4...
XAMPP: Starting Apache with SSL (and PHP5)...
XAMPP: Starting MySQL...
XAMPP: Starting ProFTPD...
XAMPP for Linux started.
```

12. Symbolic link to fix Sendmail.pm problem (see below for more details).

```
root-gpg4:i686-linux> pwd
/opt/lampp/lib/perl5/5.10.1/i686-linux
```

```
root-gpg4:i686-linux> ln -s /usr/share/perl5/Mail/Sendmail.pm Sendmail.pm <-- had to create the target directory
and copy the file into it.
```

13. Change the file names in all the input files in /opt/lampp/htdocs/enote1.12/html/gpg/. This was done using grep, cut, etc (see below) with macros in emacs to create a file with lines like the following.

```
grep text index.lst | grep -v - | cut -b 5-15 > changename.sh
```

some lines from changenames.sh

```
sed 's|clasweb.jlab.org/cgi-bin/ENOTE/enote.pl|gpg4.richmond.edu/cgi-bin/enote112.pl|' 1090005.403 > hold.txt; rm 1090005.403 ; mv hold.txt 1090005.403
sed 's|clasweb.jlab.org/cgi-bin/ENOTE/enote.pl|gpg4.richmond.edu/cgi-bin/enote112.pl|' 1090203.732 > hold.txt; rm 1090203.732 ; mv hold.txt 1090203.732
sed 's|clasweb.jlab.org/cgi-bin/ENOTE/enote.pl|gpg4.richmond.edu/cgi-bin/enote112.pl|' 1090247.767 > hold.txt; rm 1090247.767 ; mv hold.txt 1090247.767
```

There was a line for each file that contained the base entry. Then execute 'source changename.sh'.

14. Set the permissions.

```
root-gpg4:gpg> pwd
/opt/lampp/htdocs/enote1.12/html/gpg
```

```
root-gpg4:gpg> chmod o+w l*
root-gpg4:gpg> chmod o+w .
root-gpg4:gpg> chmod o+w index.lst
```

15. Turn on the www(http) service with the gui.

```
run
```

```
system-config-firewall
```

from root. running from the menu made it crash.

16. Set up the passwords.

```
htpasswd -c /opt/lampp/passwords/users gilfoyle
chmod 644 /opt/lampp/passwords/users
chmod 644 /opt/lampp/cgi-bin/.htaccess
```

```
create .htaccess in /opt/lampp/cgi-bin
```

```
gpg4:cgi-bin> more .htaccess
AuthType Basic
AuthName "elog password"
AuthUserFile /opt/lampp/passwords/users
require valid-user
```

```
edit httpd.conf
```

```
#
# AllowOverride controls what directives may be placed in .htaccess files.
# It can be "All", "None", or any combination of the keywords:
#   Options FileInfo AuthConfig Limit
#
#AllowOverride None
# since XAMPP 1.4:
#gpg AllowOverride All
AllowOverride AuthConfig <---- line 237
```

```
#
# "/opt/lampp/cgi-bin" should be changed to whatever your ScriptAliased
# CGI directory exists, if you have that configured.
#
```

```
#gpg AllowOverride None
AllowOverride AuthConfig <---- line 356
Options ExecCGI
Order allow,deny
Allow from all
```

17. Turn on VPN if you are outside UR or JLab. Go to this in your browser.

```
http://gpg4.richmond.edu/cgi-bin/enote112.pl
```

Jerry Gilfoyle's Enotebook page 349 - RC corrections for 2.6r ALTp (gpg)

[Modified Thu May 26 17:03:49 2011 (GMT) gpg]

Copied from ELOG entry.

Starting collecting results for RC correction to ALTp. Since the correction appears to be significant and different and varies with phi for the polarized and unpolarized parts of the cross section, then I have to put in the correction on each separately. (1) The first step is to generate the 2D surfaces (functions of cos(theta) and phi) for polarized and unpolarized at many different Q2 values. The first plot below shows the surfaces for polarized RC correction for Q2=0.2 GeV2 (red) and Q2=0.5 GeV2 (blue). Mathematica notebooks for separate Q2 calculations are below fig 1.

Fig 1. Comparison of 2.6r ALTp with radiative corrections on (blue) and off (red).

Jerry Gilfoyle's Enotebook page 351 - Testing RC on 2.6r (gpg)

[Modified Thu May 26 21:45:52 2011 (GMT) gpg]

I'm getting analysis results that don't have the correct histograms. Am I picking up old stuff because it is not getting deleted or copied over on the remote nodes.

2011-04-11 17:57:28

Fig 1. 2.6r ALTP results from weird software without the correct histograms. No RC or mproton cut here.

I was using an old summed histogram file on my jump drive. Dumb ass!!! For the RC in the plot below, I fixed the Q2 of the RC to 0.2 for ALL Q2 to study the effect.

Fig 2. 2.6r ALTP results with no RC (red) and RC (blue). No mproton cut here.

```

Between Figs 2-3 I discovered a mistake in the analysis code. I was using the wrong set of bin edges in eod5.C. This whole project has been plagued by me being not careful enough with all the parameters of the analysis. I must be more careful in the future. I believe that is why there are small variations from one analysis run to another when they are many months apart.

2011-04-12 12:38:15

Fig 2. 2.6r ALTP results with no RC (red) and RC (blue). No mproton cut here.

The idea her is a quick check that something pathological is not going on. I would expect small changes in the RC'ed histograms. If they were exactly the same, then we would clearly be doing something wrong. They look reasonable.

Jerry Gilfoyle's Enotebook page 352 - RC check (gpg)

[Modified Thu May 26 21:49:20 2011 (GMT) gpg]

Use the same routines in root to generate surfaces showing the ratio of pol/unpol RC to try to understand the large effect at $p_m=0.25$ GeV/c in the previous entry.

Check RC ratio, $Q^2=0.2$ GeV²

Fig 1. Ratio RC_{pol}/RC_{unpol} for $Q^2=0.2$ GeV². The range of the correction is about 0.9-1.04; much less than the 30% effect seen in the previous entry.

Click [here](#) to view the object (Root macro) you uploaded.

That was the low end of the Q^2 range now look at the high end.

Check RC ratio, $Q^2=1.5$ GeV²

Fig 2. Ratio RC_{pol}/RC_{unpol} for $Q^2=1,5$ GeV². The correction is large at low p_m and high ϕ . However, for $p_m \sim 0.2$ GeV/c the effect is about 10-15% which is much less than observed in the previous entry.

Click [here](#) to view the object (ROOT macro) you uploaded.

Jerry Gilfoyle's Enotebook page 353 - ALTp(phi) method. (gpg)

[Modified Thu May 26 21:52:19 2011 (GMT) gpg]

Check the RC by first looking at ALTp(phi) with the correction off and on. The first plot is my old, old results.

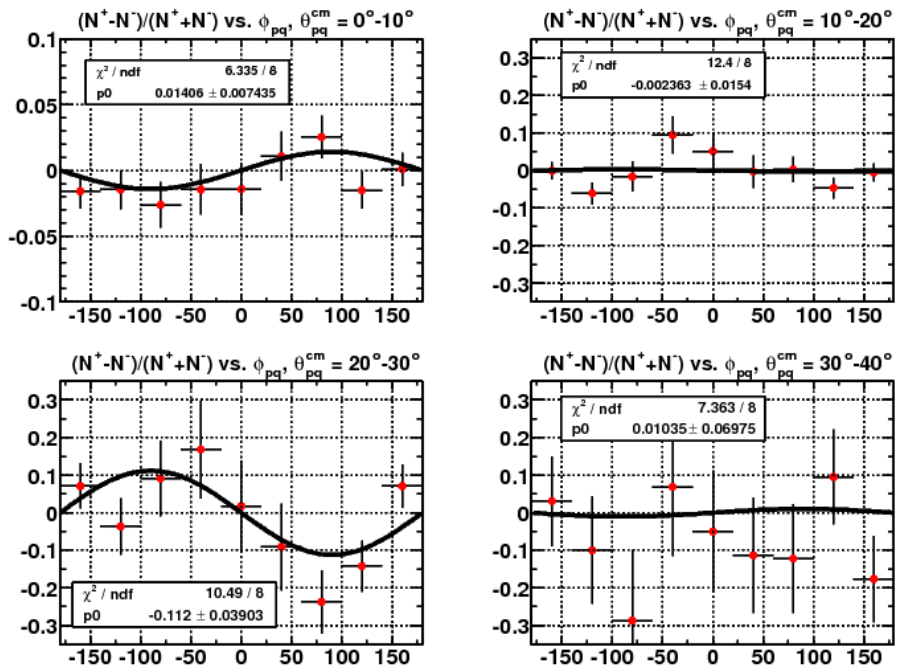

Fig 1. Analysis of phi dependence of of ALTp to extract amplitudes.

Jerry Gilfoyle's Enotebook page 354 - testing 2.6r RC correction for $p_m = 0.20-0.25$ GeV/c (gpg)

[Modified Thu May 26 22:01:03 2011 (GMT) gpg]

Print out the ratio of the polarized to unpolarized RC for 2.6r and $p_m=0.20-0.25$ GeV/c. From entry 3 it looks like I should get very few events with this ratio being greater than about 1.10-1.15 which is much less than the observed effect (about 1.5 on average) of the RC correction on ALTp (see entry 2). Fig 1 shows the ratio which looks weird. I don't understand the sharp structures around ratio = 1.0.

2011-04-17 00:02:43

Fig 1. Histogram of pol/unpol ratio event-by-event for $p_m=0.20-0.25$ for 2.6r.

Click [here](#) to view the object (Root macro) you uploaded.

Fixed the cut on the Q2 range which should have been 0.0 GeV2 (it was 0.2 GeV2) and saw an increase in the number of events from 57k to 67k, but apparently no big change in the shape.

2011-04-17 13:04:34

Fig 2. Same as Fig 1 with histogram of pol/unpol ratio event-by-event for $p_m=0.20-0.25$ for 2.6r. Fixed the cut on the Q2 range.

Getting lots of these!??

Error in : Cannot interpolate outside histogram domain.
 Error in : Cannot interpolate outside histogram domain.
 Error in : Cannot interpolate outside histogram domain.

Fixed the above by using the proper Q2 range in the limits of the interpolation of the TH3D histogram. After cleaning that up, I get the following for the 2.6r, in-range RCs for $p_m=0.2-0.25$ GeV/c which is starting to look reasonable.

2011-04-17 23:48:34

Fig 3. Same as Figs 1-2 with histogram of pol/unpol ratio event-by-event for $p_m=0.20-0.25$ for 2.6r. Really fixed the cut on the Q2 range this time.

Click [here](#) to view the object (Root macro) you uploaded.

For events with p_m , ϕ , or Q2 outside the range of the RC calculation I use the closest value of the same parameter that is in the range of the calculation, i.e. for $p_m < 0.035$ GeV/c, I set $p_m=0.035$ GeV/c and use that value to calculate the RC. Results for the out-of-range events is shown in fig 4.

2011-04-18 00:40:29

Fig 4. Same idea as figs 1-3, but now for events that are outside the range of the RC calculation.

Click [here](#) to view the object (Root macro) you uploaded.

The structures in fig 3-4 are (shoulder in fig 3 at $p_m \sim 1.04$ GeV/c, peak in fig 4 at $p_m \sim 1.02$), I am guessing, due to 'large' accumulations of events in different kinematic regions.

Jerry Gilfoyle's Enotebook page 355 - Results of fixes to 2.6r RC application (gpg)

[Modified Fri May 27 02:00:23 2011 (GMT) gpg]

After fixing the bugs in the code applying the RCs we redo the asymmetry ALTp. The first plot shows the effect is now very small consistent; consistent with the results on the distribution of RC studied in entry 5. Replaces previous results which showed a significant effect due to typos in the code. The mistake in the code was that I had

```
hp_m_unwghtplus8->Fill(missing3vec_mag/RCunpolCorr);
```

instead of the correct version (dropped the comma and the one).

```
hp_m_unwghtplus8->Fill(missing3vec_mag,1/RCunpolCorr);
```

This typo resulted in syntactically correct code which inadvertently shrank the missing momentum. Regions (e.g. $p_m=0.20-0.25$ GeV/c) with large ALTp had strength pushed to lower p_m (and shrank) while regions with small ALTp were not effected much unless strength from the high-ALTp regions flowed into it. This explains the downward shift in the first few p_m bins and the large effect on the size of ALTp right where the asymmetry was largest. At large p_m (>0.25 GeV/c) there was not much there to start with and no large-ALTp regions fed those bins. The effect on ALTp is shown below.

2011-04-18 08:40:55

Fig 1. Comparison of ALTp for 2.6r with RC on (blue) and RC off (red) showing the fall effect of the RC.

```

Put in the full set of pm-phi_pq surfaces for the proper set of Q2 values and get the following. The effect of the RC is small.

Fig 3. Comparison of 2.6r ALTp with RC off (red) and on (blue). Effect is small.

Click [here](#) to view the object (Root macro) you uploaded.

After putting in the full set of pm-phi_pq surfaces for each value of Q2 in the TH3D histogram I get the following results for the RC for 2.6r.

2011-04-19 17:20:03

Fig 4. Uncertainty on the RC for 2.6r.

Click [here](#) to view the object (Root macro) you uploaded.

Check the distribution of RC factors for events in and out of the applicable range of the EXCLURAD calculation. Outside the range we just assign the out-of-range parameter the value of the nearest limit.

2011-04-19 18:18:30

Fig 5. For 2.6r events that are outside the range of the RC calculation for EXCLURAD.

Click [here](#) to view the object (Root macro) you uploaded.

For in-range events there are more counts at low RCpol/RCunpol which accounts for the observation that ALTp has a larger amplitude (deeper dip) for pm=0.2-0.25 GeV/c.

Fig 6. For 2.6r events that are in the range of the RC calculation for EXCLURAD.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 356 - turn on 2.6r mp cut (gpg)

[Modified Fri May 27 03:49:15 2011 (GMT) gpg]

Turn on the proton mass cut that is used to eliminate the funky wings on the momentum versus mass distribution that are due to events associated with the wrong beam bucket.

2011-04-20 00:08:16

Fig 1. Comparison of ALTp for 2.6r with the Mp cut turned for RC on (blue) and off (red).

Click [here](#) to view the object (Root macro) you uploaded.

Compare results with no mp cut turned on and things look much the same except for $p_m = 0.3$ GeV/c.

2011-04-20 00:18:31

Fig 2. Comparison of mp cut on (red and blue), RC on (blue and black), and RC off (red).

Click [here](#) to view the object (ROOT macro) you uploaded.

Jerry Gilfoyle's Enotebook page 357 - Effect of RC and mp cut on 2.6n ALTp (gpg)

[Modified Fri May 27 20:25:21 2011 (GMT) gpg]

Now get ALTp with mp cut on and compared RC on/off. RC effect is small; mp cut is small comparing with 2.6n ALTp in CAN.

2011-04-20 11:31:55
Fig 1. Comparison of ALTp with RC on (blue) and off (red). Both asymmetries have the mp cut on.

Click [here](#) to view the object (Root macro) you uploaded.

Turn off mp cut and check the results. First show 2.6n ALTp from the CAN draft.

Fig 2. 2.6n ALTp from CAN draft.

Now get the latest results with no mp cut.

2011-04-20 13:53:02

Fig 3. 2.6n ALTp with no mp cut and RC on (blue) and off (red).

Click [here](#) to view the object (Root macro) you uploaded.

The effect of the mp cut is VERY small.

Jerry Gilfoyle's Enotebook page 358 - Effect of efids/pfids with mp and RC on 2.6n (gpg)

[Modified Thu Jun 2 11:14:36 2011 (GMT) gpg]

Now check the effect of the fiducial cuts. I am rethinking the argument to turn them off in the analysis. My thought is that we must trust that this asymmetry is special and we are really dividing by the same acceptance in the denominator. I believe (and will check this) that turning on the fiducials removes many low-Q2 event that fall outside the standard acceptance. Any difference between the fids on and fids off may be attributed to this difference in the Q2 distribution. There is no obvious way to check this since these excluded events are not included in the standard class acceptance. I may just punt the whole idea.

2011-04-24 20:41:58

Fig 1. Comparison of ALTp for 2.6n with fids on (red) and off (blue).

Click [here](#) to view the object (Root macro) you uploaded.

Look at the difference between ALTp with and without fiducial cuts in Fig 2a. Can't do the uncertainties here yet because the two data sets are NOT independent. However, in Fig 2b we extract dALTp from the histograms with the fiducials turned on and the histograms of the events excluded by the fiducial cuts. These data sets are independent so we can calculate uncertainties for them (see below). The difference between the two distributions is not understood (Now it is, see below).

2011-04-24 21:01:44

Fig 2a. Difference between 2.6n ALTp with and without efids/pfids as a function of pm.

2011-04-25 15:38:55

Fig 2b. Extracted difference between 2.6n ALTp with and without efids/pfids as a function of pm.

Click [here](#) to view the object (Root macro) you uploaded.

Take a look at the different Q2 distributions with the fids on (red) and off (black). Fids on (red) is scaled by 1.8068.

2011-04-24 23:57:11

Fig 3. Comparison of electron singles vs. Q2 for 2.6n with fids on (red) and off (black). Fids on (red) is scaled up by 1.8068.

Click [here](#) to view the object (Root macro) you uploaded.

There are inadequate statistics to test the no-fids for the QE ALTp so turn off the QE requirement and maybe the proton requirement to see if we can get something to compare fids on/off with decent stats.

Extracted dALTp with uncertainties calculated with Sumw2() option in ROOT. See log-11-apr-25 for details.

2011-04-25 16:36:50

Fig 4. Extracted dALTp for 2.6n with mp, RC etc. and proper calculation of uncertainties.

Click [here](#) to view the object (Root macro) you uploaded.

The problem in Fig 2 was due to the fact that I left out the beam polarization correction for the extracted delta ALTp. When I put that in I get perfect agreement.

2011-04-25 17:52:22

Fig 5a. Difference between 2.6n ALTP with and without efits/pfids as a function of p_m (same as 2a).

Jerry Gilfoyle's Enotebook page 359 - Generated vs Reconstructed Electron Theta (Mark Moog)**[Modified Thu Jun 2 11:23:04 2011 (GMT) Mark Moog]**

This is a comparison of generated theta to reconstructed theta. It is very good which means if we calculate electron momentum using reconstructed theta, it will be very close to the generated electron momentum. Thus we can use this number to cut out electrons that have reconstructed momenta far from the theta derived momentum and instead of using generated momentum.

gen theta vs recon theta

Jerry Gilfoyle's Enotebook page 360 - Minimum electron angle in CLAS12 (gpg)

[Modified Thu Jun 2 17:28:55 2011 (GMT) gpg]

The results below were from a study using the interactive gemc. From log-11-jan-07,

look for hits in 3 DC superlayers and in tof

```
E' = 9.05 GeV, theta = 9.0, yes
E' = 9.05 GeV, theta = 11.0, yes
E' = 9.05 GeV, theta = 7.0, yes for DC, no for TOF
E' = 9.05 GeV, theta = 7.5, yes for DC, no for TOF
E' = 9.05 GeV, theta = 7.6, yes for DC, no for TOF
E' = 9.05 GeV, theta = 7.7, yes for DC, no for TOF
E' = 9.05 GeV, theta = 7.8, yes
E' = 9.05 GeV, theta = 8.0, yes
```

```
E' = 9.05 GeV, theta = 5.0, yes for DC R1+R2, no for R3, no for TOF see minimumElectronAngle3.gif
E' = 9.05 GeV, theta = 6.0, yes for DC R1+R2, 1 hit for R3, no for TOF
E' = 9.05 GeV, theta = 7.0, yes for DC R1+R2, 7 hits for R3, no for TOF
E' = 9.05 GeV, theta = 4.0, no hits in DC, no for TOF
E' = 9.05 GeV, theta = 4.5, 1 hit in DC R1 only, no for TOF
```

Now study elastic scattering in CLAS12 with gemc to see where we start to lose the TOFs. The table below gives the E' as a function of θ and θ .

θ	E'	θ	E'	θ	E'	θ	E'
0.	11000.	3.	10826.3	6.	10337.	9.	9614.21

Jerry Gilfoyle's Enotebook page 362 - Return to NDE - impact of Edep cut (gpg)

[Modified Mon Jun 13 16:41:51 2011 (GMT) gpg]

We are returning to our study of the neutron detection efficiency in CLAS12. The problem is the surprising sensitivity of the NDE to the cut we put on Edep. See Figs 1-2 below. In Fig 1 the Edep threshold was chosen so the NDE from CLAS12 TOF would agree with the value for E5. This sensitivity to the Edep threshold just doesn't look right.

Found Neutron Momentum in P1A

2011-06-08 12:34:49

Fig 1a. Comparison of neutron momentum distribution for found and reconstructed neutrons.

Click [here](#) to view the object (Root macro) you uploaded.

NDE for P1A

2011-06-08 12:42:31

Fig 1b. Neutron detection efficiency extracted from the adjacent figure compared with E5 result.

Click [here](#) to view the object (Root macro) you uploaded.

Now turn the threshold down to the minimum so we take any hit at all and the NDE goes up dramatically. There is clearly something wrong with this approach.

2011-06-08 12:44:10

Fig 2a. Comparison of neutron momentum distribution for found and reconstructed neutrons with Edep > 0.

Click [here](#) to view the object (Root macro) you uploaded.

2011-06-08 12:46:06

Fig 2b. Neutron detection efficiency extracted from the adjacent figure.

Click [here](#) to view the object (Root macro) you uploaded.

Now look at various distributions of the NDE analysis at the place we left off last February. The selection of the neutrons was based on the following cuts.

```
neu_found_p1a[BestElectron] - a neutron has been found.
fabs(best_deltap)theta_emin - avoid electron tracks without full set of wire hits (10 deg).
r_theta[BestElectron]< gamma_cut - gamma cut (10 deg)
Edep_p1a[c] > edep_cut - Edep cut
```

Results are below for neutrons with Edep > 33 MeV in each scintillator layer.

Fig 3. Results of NDE analysis for $E_{dep} < 33 \text{ MeV}$, $\gamma < 10 \text{ deg}$.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now turn the Edep cut down to zero (see the effect above in 2b) and require a neutron using pid_p1a.

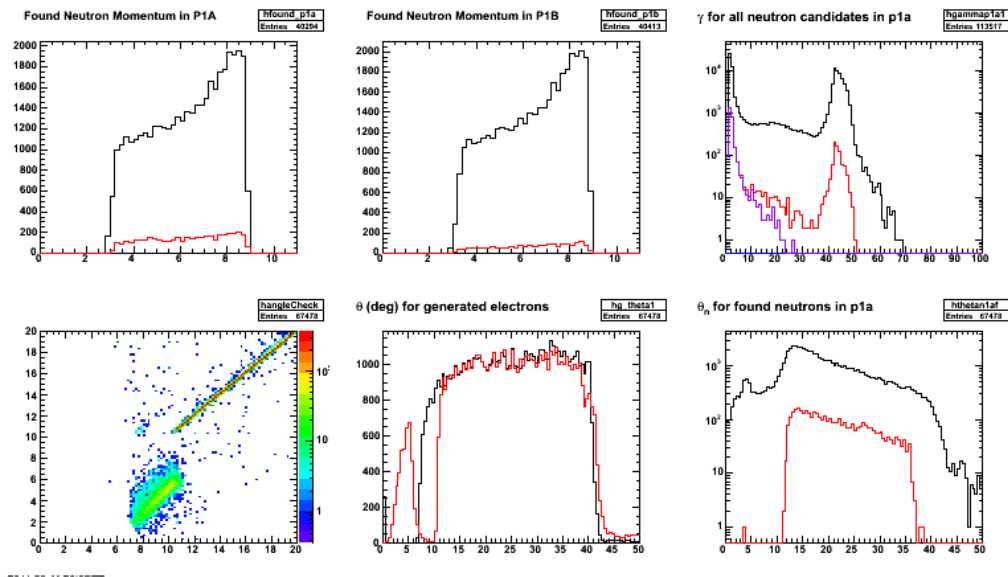

Fig 4. Results of NDE analysis for $E_{dep} > 0$ MeV, $\gamma < 10$ deg, and $pid_{p1a}=2112$.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Remove the γ cut and see what happens to NDE.

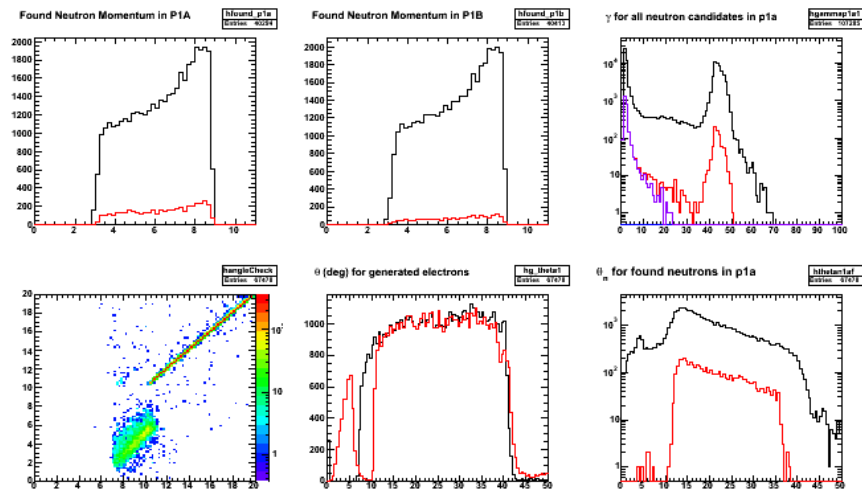

Fig 5. Results of NDE analysis for $E_{dep} > 0$ MeV and $pid_{p1a}=2112$ and no γ cut.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now turn on ONLY the angle cut. Only did it for $gammap1a$ and not the other panels.

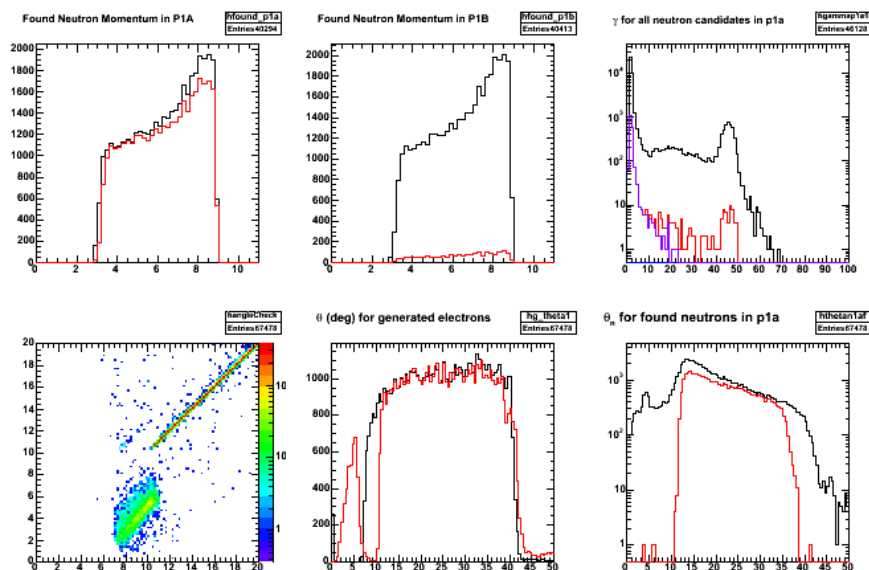

Fig 6. Results of NDE analysis for $\gamma < 10$ deg ONLY.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now turn on the γ cut and just the $E_{dep} > 0$ requirement. This is the closest we will have to the experimental situation modulo any threshold on the ADCs and TDCs of the TOFs.

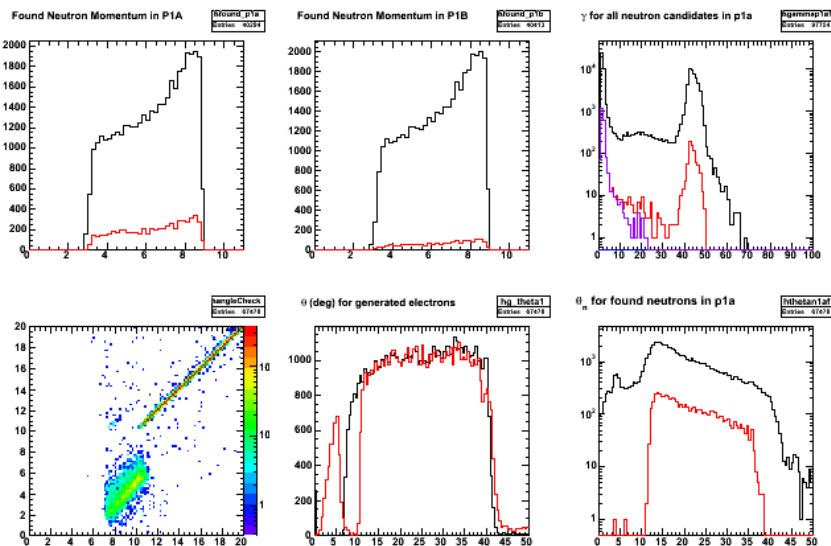

Fig 7. Results of NDE analysis for $\gamma < 10$ deg and $E_{dep} > 0$.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Now just require a neutron hit and the efficiency again goes close to 1.0.

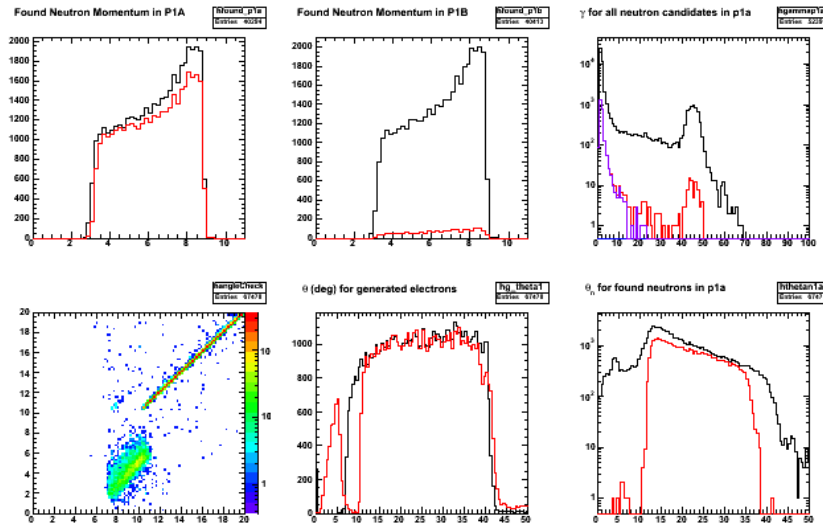

Fig 8. Results of NDE analysis for pid_p1a=2112 ONLY.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Analysis code) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Take a look at the efficiencies. A summary

1. Whenever there is no Edep cut the efficiency is close to one because there are always hits in the right spot of the TOF. In a real experiment those Edep=0 hits would never show up.
2. With the γ cut, $E_{dep} > 0$, and requiring pid=2212 we get an efficiency of about 0.10.
3. With the γ cut and $E_{dep} > 0$ we get an efficiency of about 0.15. Why does it go up significantly with a less reliable cut? Are we picking up some background? From where? We only have QE neutrons in the generator.

Part of the answer: With the PID cut off we get about half as many photon hits as neutron hits. Where are they from? Neutron rattling around inside the DCs? Look at the TDCs to see if I can separate them.

Particle species for no pid cut with γ and Edep cuts on.

```
TH1.Print Name = hpid, Entries= 6069, Total sum= 6061
fSumw[2090]=189, x=-210.5
fSumw[2287]=1, x=-13.5
fSumw[2288]=4, x=-12.5

Jerry Gilfoyle's Enotebook page 363 - Missing Mass Update (Moog)

[Modified Sat Jun 18 15:01:58 2011 (GMT) Moog]

The missing mass plot is very wide, which is unexpected since the electron momentum plot isn't wide. After checking my missing mass calculation, I decided to see if missing mass had a dependency on some other variable (which it shouldn't.) First I looked at missing mass vs electron momentum and saw some sort of dependency.

Note added later (6/18/11): After comparing $\Delta p/p$ distributions with JSocrat (see entry 364) it appears that distribution is consistent with JSocrat and with the results published in CLAS Note 2008-015 by Sebastien. We are calculating MM^2 correctly (I think) so the width of the MM^2 distribution is expected from the width of $\Delta p/p$. The curve in the plot of momentum versus missing mass is due to energy loss which is larger in percent at low momentum than at higher momentum. I haven't seen this in the E5 analysis because we use elastic scattering for the momentum corrections and that includes the energy loss correction.

Missing Mass

2011-06-10 11:08:51

Click [here](#) to view the object (ROOT Macro) you uploaded.

Missing Mass vs Reconstructed Electron Momentum

2011-06-10 11:10:43

Click [here](#) to view the object (ROOT Macro) you uploaded.

Then I looked at missing mass against the generated momentum delta, (calculated with [reconstructed momentum - generated momentum] / generated momentum.) There is definitely a relationship. I next looked at the from theta momentum delta (calculated with [reconstructed momentum - momentum from reconstructed theta] / momentum from reconstructed theta.) There is a very clear one-to-one relationship here, and missing mass is very sensitive to changes in the from these momentum deltas.

Missing Mass vs Electron Momentum Delta (gen - recon)

Missing Mass vs Electron Momentum Delta (from theta - recon)

2011-06-10 11:14:45

Click [here](#) to view the object (ROOT Macro) you uploaded.

Consider the following table. Many events have electron and neutron momenta that are very different from the expected values. The analysis here was done on an

generated event file that had 220 copies of the same event in the event generator input file. These events were then passed through gemc, gemc_evio2root, and Socrat. This is the Socrat output. The 'bad' events seem to be roughly correlated with a large number of hits in the DC; too many noise hits?

24	74	11	7.3311870	7.4782856	2112	4.5116191	4.4087492

The input event in LUND format:

```

      2  1  0  0  0  1.000  0.334  0.883  6.894  3.669
0  -1  1  11  0  0  1.3393  1.6441  7.0178  7.3312  0.0005  0.0000  0.0000  0.0000
1  0  1  2112  0  0  -1.3393  -1.6441  3.9822  4.5116  0.9396  0.0000  0.0000  0.0000

```

The events with a large difference with the generated momentum however are not included in our usual analysis. We already exclude them with the $\Delta p/p < 0.10$ cut. The correlation with the number of hits (ndchits) is very rough; event no. 13 in the table above has a large momentum difference but ndchits=76 which is typical for 'good' events.

Jerry Gilfoyle's Enotebook page 364 - Comparison of $\Delta p / P$ (Mark Moog)

[Modified Sat Jun 18 14:48:35 2011 (GMT) Mark Moog]

2011-06-13 14:21:18

Click [here](#) to view the object () you uploaded.

Agreed, but this is still too wide. The momentum resolution of CLAS12 should be about 5%. Actually, maybe not. The plot below shows the distribution and RCS value for the central peak. The large value of the RMS above was due to the high $\Delta p/p$ tail. In the region of the central peak the value of the width is reasonable at about 3%.

Fig 2a. $\Delta p/p$ from long gemc run.

Fig 2b. Full range plot of 2a.

Click [here](#) to view the object (Root macro) you uploaded.

The plot below shows the distribution generated from the event file made of 220 copies of the same event that I generated for testing purposes. This is not the greatest, most consistent test, but the results are similar.

Fig 3. Distribution generated by Sebouh from the file with 220 copies of the same event.

Jerry Gilfoyle's Enotebook page 365 - Testing the 2.6n, no-fids analysis (gpg)

[Modified Wed Jun 15 03:22:00 2011 (GMT) gpg]

Compare fids on/off for ALTp with non QE in order to get more statistics. Use $Q^2=0.8-1.5$ since the two Q^2 distributions for 2.6n, fids on and fids off look similar. See fig 1. The right-hand panel has the fids on distribution scaled to match the high- Q^2 drop and they look similar for $Q^2=0.5-1.5$ GeV².

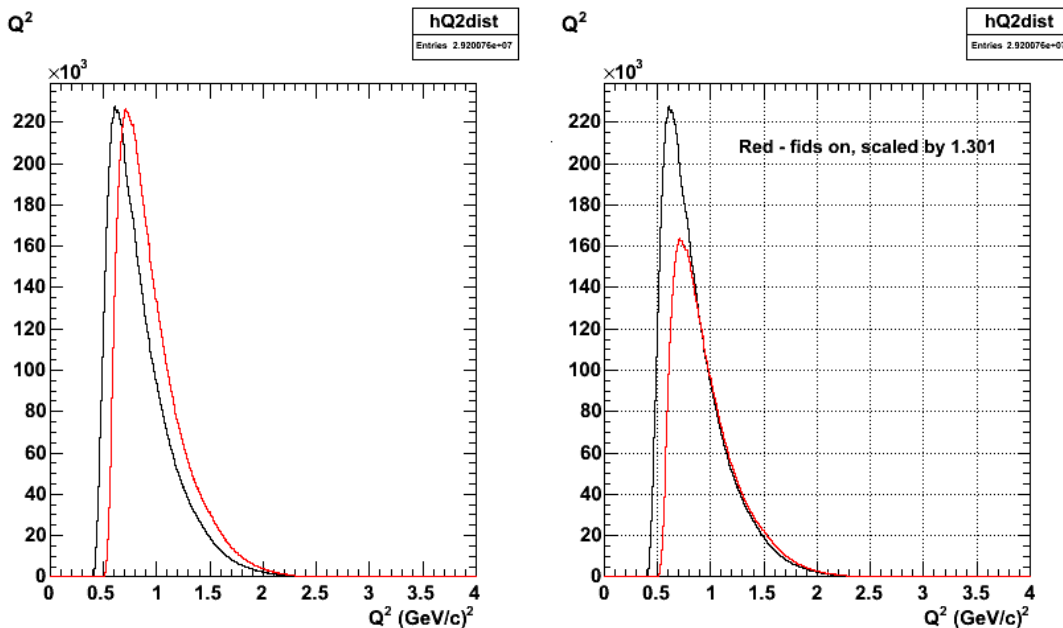

Fig 1. Comparison of Q^2 distribution for fids on (red) and off (black) scaled to make the comparison easier.

Click [here](#) to view the object (Root macro) you uploaded.

Results from relaxing the QE requirement and cutting on $Q^2=0.8-1.5$ GeV². The asymmetry here is very small so this doesn't help.

Fig 2. Helicity asymmetry for 2.6n with no QE cut and $Q^2=0.8-1.5$ GeV².

Click [here](#) to view the object (Root macro) you uploaded.

Now turn off the MM2 cut to isolate neutrons.

Fig 3. Same as fig 2 with MM2 neutron cut turned off. Fitting a straight line to dALTP I get $p_0 = 0.00019 \pm 0.0017$ with $\text{chisq}/\text{ndf} = 1.6/8$.

Click [here](#) to view the object (Root macro) you uploaded.

Now turn off the RC because I am getting lots of outside-the-interpolation-range messages.

Fig 4. Same as fig 3 with RC off because of error messages.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Tar archive/backup of the analysis code eod5c is attached.) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Jerry Gilfoyle's Enotebook page 366 - testing the 2.6r no-fids analysis (gpg)

[Modified Sun Jun 19 16:39:45 2011 (GMT) gpg]

First compare the electron singles Q2 distribution with fids on and off.

2011-04-28 10:01:48

Fig 1. Comparison of 2.6r ALTP for e fids/pfids on (red) and off (blue).

Click [here](#) to view the object (Root macro) you uploaded.

Now look at the electron singles Q2 distribution for e fids/pfids on/off. They both cover the same Q2 range! Left-hand panel shows unmodified distribution while right-hand panels shows the same distributions with the e fids/pfids on distribution in red scaled by 1.81 to match the scale of the e fids/pfids off.

Fig 2. Comparison of electron Q2 distribution for 2.6r for e fids/pfids on (red) and off (black).

Click [here](#) to view the object (Root macro) you uploaded.

Now compare ALTP with e fids/pfids on and off. The difference between the two is consistent with zero (see fit results in right-hand panel of Fig 3), but the uncertainties are large. The uncertainties here were calculated by treating the no e fid/pfid results as the sum of e fids pfids on + events excluded by the fiducials. In this way we have two independent sets of events so we can use standard techniques for calculating the uncertainties.

Fig 3. Comparison of ALTp with efids/pfids on (red) and off (blue) in the left-hand panel. The right-hand panel shows the difference between the two with uncertainties. Histogram file is listed below.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

To get more statistics in the comparison of ALTp with efids/pfids on/off turn off the QE cut for the ALTp histograms and set epn_event=true for all events.

Fig 4. Helicity asymmetry (left-hand panel) for 2.6r with no QE cut, no MM2 cut, and no Q2 cut to improve statistics with efids/pfids off (blue) and on (red). The difference between those two distributions is shown in the right-hand panel. See below for histogram file.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root histogram file) you uploaded.

Jerry Gilfoyle's Enotebook page 367 - Doing 2.6r delta_ALTp correctly (gpg)

[Modified Sun Jun 19 16:47:44 2011 (GMT) gpg]

As I think about the dALTp analysis from the previous entries I realized I did it wrong. In order to get the uncertainties correctly added together the quantities have to be from independent data sets. When I constructed the nofids ALTp using the sum of fids+out (where out means outside the efids/pfids cut) I violated that requirement. This summed distribution is manifestly NOT independent of the nofids distribution because it contains events that are in the nofids ALTp. When I calculate dALTp I have to use two, statistically independent data sets. The ones on hand are the fids and the out distributions so calculate the difference between those and then the uncertainties can be properly calculated.

Results below were extracted from histogram files in entry 11.

First calculate ALTp for fids, nofids, and out.

2011-04-30 11:10:05
Fig 1. Comparison of 2.6r ALTp for fids on (red), fids off (blue), and outside fids (green).

Click [here](#) to view the object (Root macro) you uploaded.

Now calculate the difference dALTp between the fids on ALTp and the fids out ALTp for 2.6r. The results are not that different from the previous ones for the difference between ALTp with fids on and ALTp with fids off. That bodes well for when I enhance the stats.

Extracted $\Delta A'_{LT}$

2011-04-30 11:29:47

Fig 2. dALTP for 2.6r and QE events. Note: the label 2.6n on the plot is wrong.

Click [here](#) to view the object (Root macro) you uploaded.

Compare the asymmetries as in Fig 1, but now for fids on, fids off, fids out for no QE and MM2 cuts to enhance the statistics.

2011-04-30 11:43:41
 Fig 3. Comparison of ALTP for fids on (red), fids off (blue), and fids out (green) as in Fig 1.

Click [here](#) to view the object (Root macro) you uploaded.

Compare dALTP between fids on and fids out. The result is 1.3 sigma away from zero.

Extracted $\Delta A'_{LT}$

2011-04-30 11:49:06
 Fig 4. Same as fig 2 for 2.6r, but now with QE and MM2 cuts off.

Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 368 - Do 2.6n delta_ALTp correctly. (gpg)

[Modified Sun Jun 19 17:21:44 2011 (GMT) gpg]

Now do the 2.6n dALTp analysis correctly as described in the previous entry (12). Do the enhanced stats analysis right away (no QE, MM2 cuts with $Q^2=0.8-1.5$ GeV²). The statistics are still rather lousy.

2011-04-30 13:26:19

Fig 1a. Comparison of ALTp for efids on (red), fids off (blue), and outside the fids (green).

Click [here](#) to view the object (Root macro) you uploaded.
Here is ALTp with the QE and MM2 cuts on.

Jerry Gilfoyle's Enotebook page 372 - Ratio of triggers to simulated QE events (gpg)**[Modified Mon Jun 20 00:31:08 2011 (GMT) gpg 1**

In preparation for the JLab IT readiness review for CLAS12 we need to estimate the ratio of simulated events to actual collected data. The old TDR for CLAS12 had a ratio of 4 simulated events for each collected one, but the recent estimate from Dennis Weygand is very different. Instead of 4:1 it is 1:5; a factor of 20 difference. For grins I estimated the number of QE simulated events versus data triggers for the E5 EOD analysis. The results are the following.

2.6n+2.6r triggers	2.6n+2.6r QE simulations
1.5*10 ⁹	2.1*10 ⁸

The ratio is simulated/collected is 0.13 versus Dennis' 0.2 which is not widely different especially since we could use more simulated events. The attached Mathematica notebook has more details. See also the following link for information on GMn. <http://clasweb.jlab.org/rungroups/e5/>

Jerry Gilfoyle's Enotebook page 373 - Non/Noff ratio (gpg)

[Modified Mon Jun 20 00:39:53 2011 (GMT) gpg 1

For the Analysis Note I have come up with a relationship between the efids/pfids on ALTp and efids/pfids off ALTp. The relationship is

$$dALTp = ALTp(on) - ALTp(out) = (ALTp(on)-ALTp(off))/(1 - Non/Noff)$$

so I need the ratio of Non/Noff.

Data Set	h=+	h=-	file
2.6r	0.38	0.38	e11f3.root
2.6n	0.52	0.52	summed_hists-11-apr-25.root

Raw numbers are below. File e11f3.root is from entry 11 in the ELOG elog. File summed_hists-11-apr-25.root is from entry 9 in the ELOG elog.

Jerry Gilfoyle's Enotebook page 374 - Energy Deposited in P1B (Mark Moog)

[Modified Thu Jun 30 17:51:42 2011 (GMT) Mark Moog]

Current energy deposited info can be found [here](#)

Energy Deposited vs. Momentum (P1B, e)

2011-06-20 15:31:04

There appears to be a cut at 10 MeV, but other than that energy deposited by the electron seems pretty uniform across all generated energies

Click [here](#) to view the object (Electron Edep ROOT Macro) you uploaded.

There is a drop, but not a cut at 10 MeV. See the next plot. Turn off everything in from of p1b; we need to understand this structure.

Energy Deposited vs. Momentum (P1B, e)

2011-06-22 13:46:09

Fig 2. Projection of Fig 1. along the Edep axis.

Jerry Gilfoyle's Enotebook page 375 - Luminosity study (gpg)

[Modified Wed Jun 22 19:47:00 2011 (GMT) gpg]

To run gemc with the luminosity use the following command

```
gemc -gcard=modified.gcard -N=1 -BEAM_P="e-, 9.0*GeV, 25.0*deg, 0.0*deg" -USE_PHYSICSL=gemc -LUMI_P="e-, 11*GeV, 0*deg, 0*deg" -LUMI_EVENT="28200, 60*ns
```

where the bunch time is 2 ns, the time window for the forward TOF system is 60 ns (this is the sum of the electronics window, plus propagation times, and the particle/event (28200) is the product of the time window and the electron rate which is 4.7×10^{11} electrons/s for the CLAS12 luminosity of $10^{35} \text{s}^{-1} \text{cm}^{-2}$. The gemc picture of the background is below.

Fig 1. Event display for gemc run with the above command including the luminosity effects.

Jerry Gilfoyle's Enotebook page 376 - OTOF Energy Deposited Update (Mark Moog)

[Modified Thu Jun 30 17:51:32 2011 (GMT) Mark Moog]

Current energy deposited info can be found [here](#)

My previous plot is incorrect since it only shows energy deposited during found events. This makes it misleading and reduces the number of data points at higher electron energies. This is a plot of energy deposited vs. momentum for 50,000 electrons (no cuts at all) shot at 25 degrees theta with a phi range of 0 to 360, and a momentum range of 3.5 to 9.5. Luminosity was also set to 0 to eliminate background.

NOTE: There is a problem with several of the spectra below showing Edep with cuts on the energy (E) of the particle as it enters the geant4 volume. In particular, I did not have the binning correct and the cuts on E are not what I thought they were. The screaming, loud-and-clear, sign of this (that I missed) is that, for example, red histograms in the lower, right panels of Figs 4-5 show Edep greater than the maximum value of the energy allowed in the event. This can't happen. I have redone Figs 3-5; see Figs 7-8.

The explanation of the spectra is still valid.

To understand the shape of the deposited energy for electrons consider the following plot. This is for electrons fired at the center of the TOF panel p1a with a broad range of momenta. I used the ntuple file listed above. In the upper left panel Edep has the characteristic shape with a peak around 10 MeV due, we believe, to relativistic electrons that are minimum ionizing particles (MIPs) so they all dump about the same amount of energy in the scintillator. The counts below 10 MeV are likely due to low-energy Moeller electrons, etc knocked loose by the passing primary electron which then stop in the plastic; producing a range of Edep that goes down to zero. The upper right panel shows Edep vs. E where E is the energy of the electron as it enters the scintillator (check with MU). The ridge at Edep ~ 10 MeV from MIPs is clearly visible across a wide range of energies and there are very few events less than 10 MeV. All of these events are clusters at E ~ 0 MeV. When I project out the Edep for low-E events (E < 5 MeV) it captures almost all the events below the MIPs. When I project out events with E > 5 MeV I get almost all MIPs with few of the E < 5 MeV events.

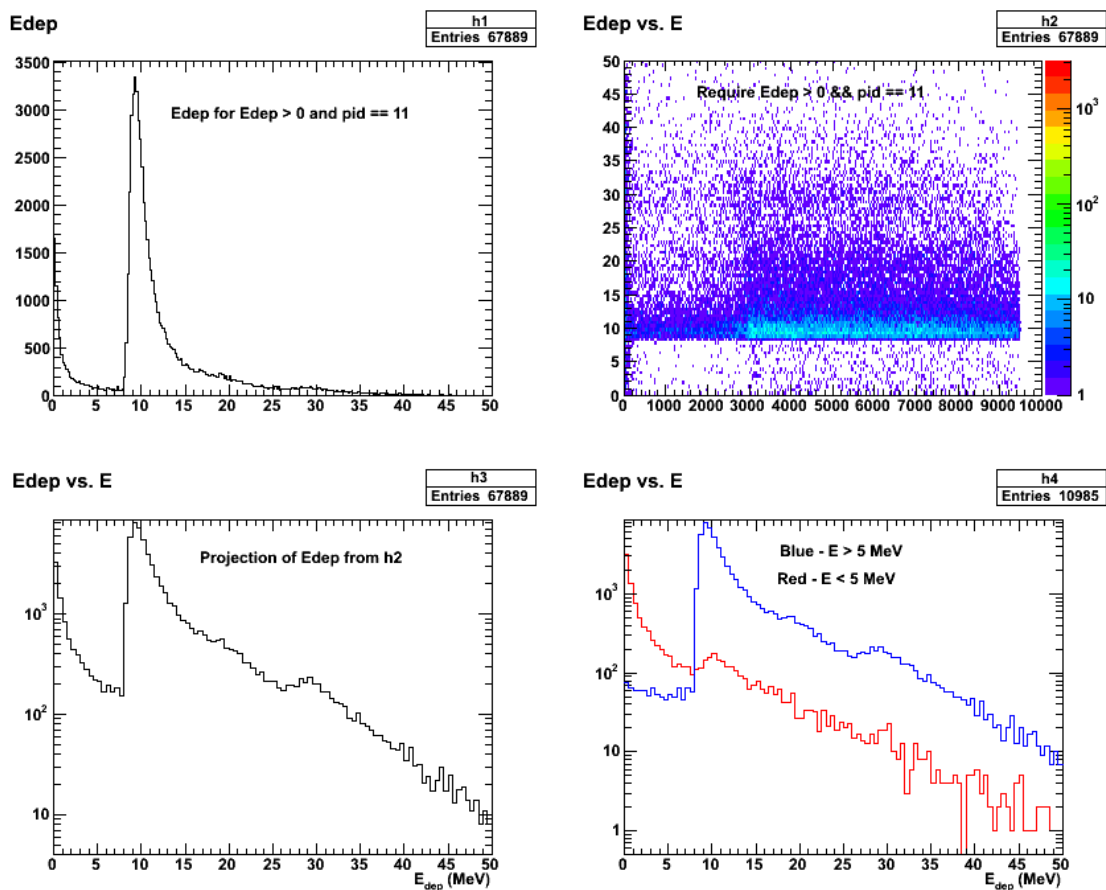

Fig 3. Plots of Edep, Edep vs. E, and projections of Edep for different E ranges (lower right panel). See text.

Click [here](#) to view the object (Root macro) you uploaded.

Do a better test on panel p1a with a single electron momentum ($p = 6.25$ GeV) and the separation between the primary electrons and Moellers becomes very clear (see plots in right-hand side of figure below). Generated with the following command on jlab12.

```
genc -USE_QT=0 -OUTPUT="evio, mptest.ev" -N=5000 -HALL_MATERIAL=Vacuum -gcard=p1a.gcard -USE_PHYSICSL=genc -BEAM_P="e-,6.25*GeV, 25*deg, 0*deg" -SPREAL
```

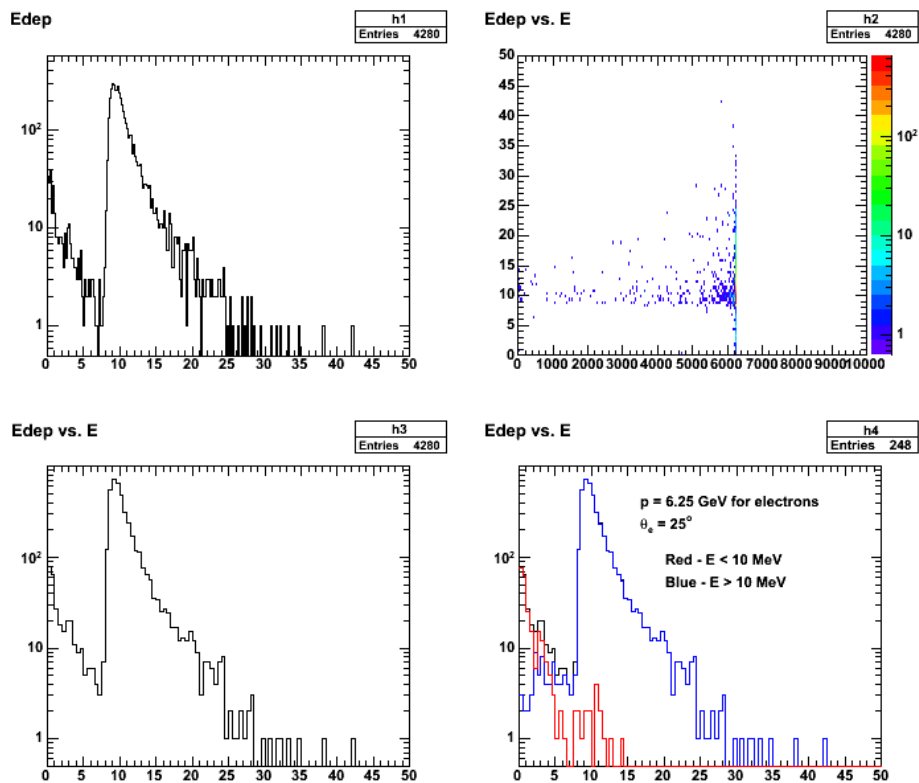

Fig 4. Plots for p1a of Edep, Edep vs. E, and projections of Edep for $p_e=6.25$ GeV/c at $\theta_e= 25$ deg.

Click [here](#) to view the object (Root macro) you uploaded.

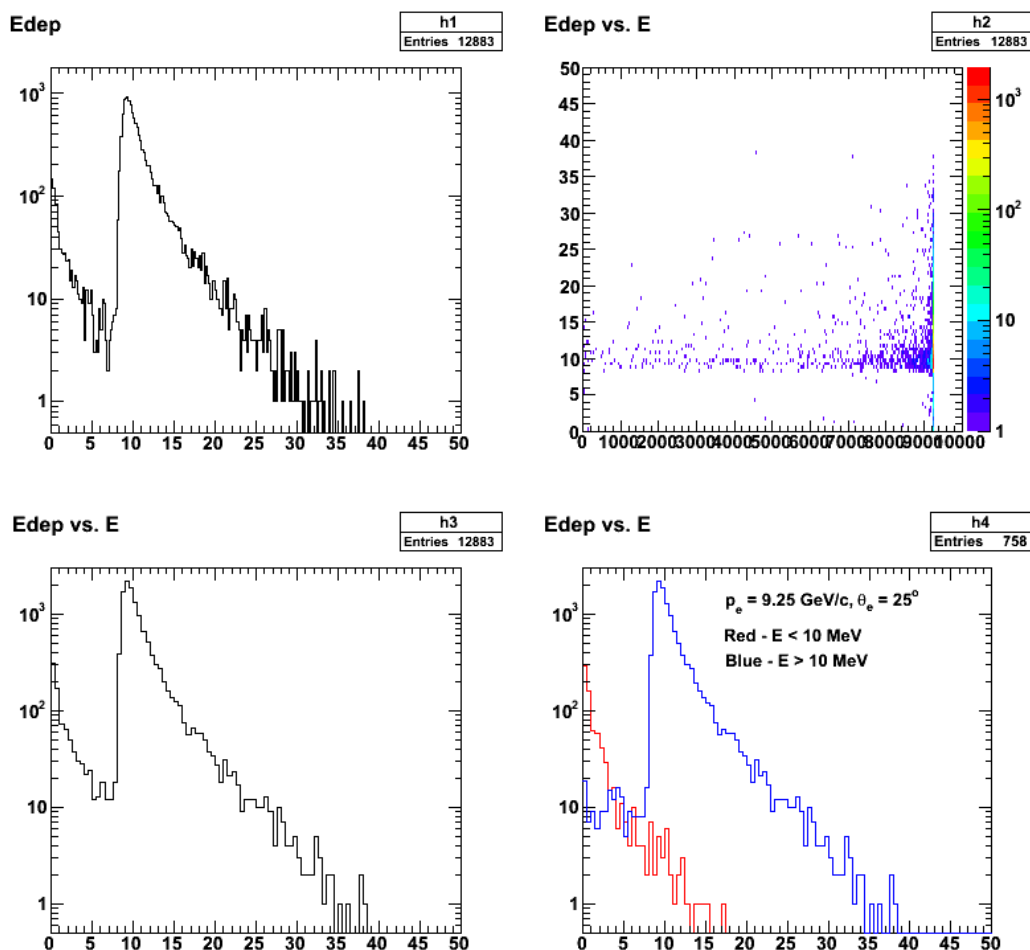

FIG 5. Plots for p1a of Edep, Edep vs. E, and projections of Edep for $p_e=9.25$ GeV/c at $\theta_e= 25$ deg.

Click [here](#) to view the object (Root macro) you uploaded.

After talking with Elton on Wed (7/13/11) we now believe the low-Edep, high-E events are due to bremsstrahlung. An electron enters the material, accelerates, and emits a forward-going photon carrying away most the initial electron momentum. Some of these electrons have energies below 10 MeV so they stop in the material producing a signal smaller than a MIP. The cross section for bremsstrahlung is supposedly bigger than for backscattering (another source of low-Edep, high-E events). To get some idea of the numbers I looked in the PDG section on 'Passage of particles through matter.' At large $y=k/E$ which is the ratio of the emitted, bremsstrahlung photon energy to the primary electron energy there is still a large cross section; about 0.5 barn! To get some idea of the backscatter cross section I assumed it was essentially elastic scattering off a proton and I get of the order of 10^{-14} mb/sr for $\theta_e > 136$ deg.

Click [here](#) to view the object (Bremsstrahlung calculations) you uploaded.

Click [here](#) to view the object (PDG - Passages of particles through matter) you uploaded.

The other mystery in the plots above is the small, but nonzero fraction of events in the tail just below the primary electron energy. Supposedly the hall has been pumped out (-HALL_MATERIAL=Vacuum) so I thought nothing should happen to the electron between the target the scintillator panel. This is wrong. Looking at several events interactively (see example below), some electrons emit bremsstrahlung photons before the electron reaches the TOF panel. This would account for those events.

Fig 6. Event display for p1a of an electron that emits bremsstrahlung photon before reaching the TOF panel p1a.

Revised versions of Fig 4-5. Start with a plot which also shows the 2D plots. The lower, right-hand panel shows the Edep vs E spectrum at low Edep and E to see the linear dependence of between the two which makes sense since you can't deposit more energy than you bring into the volume.

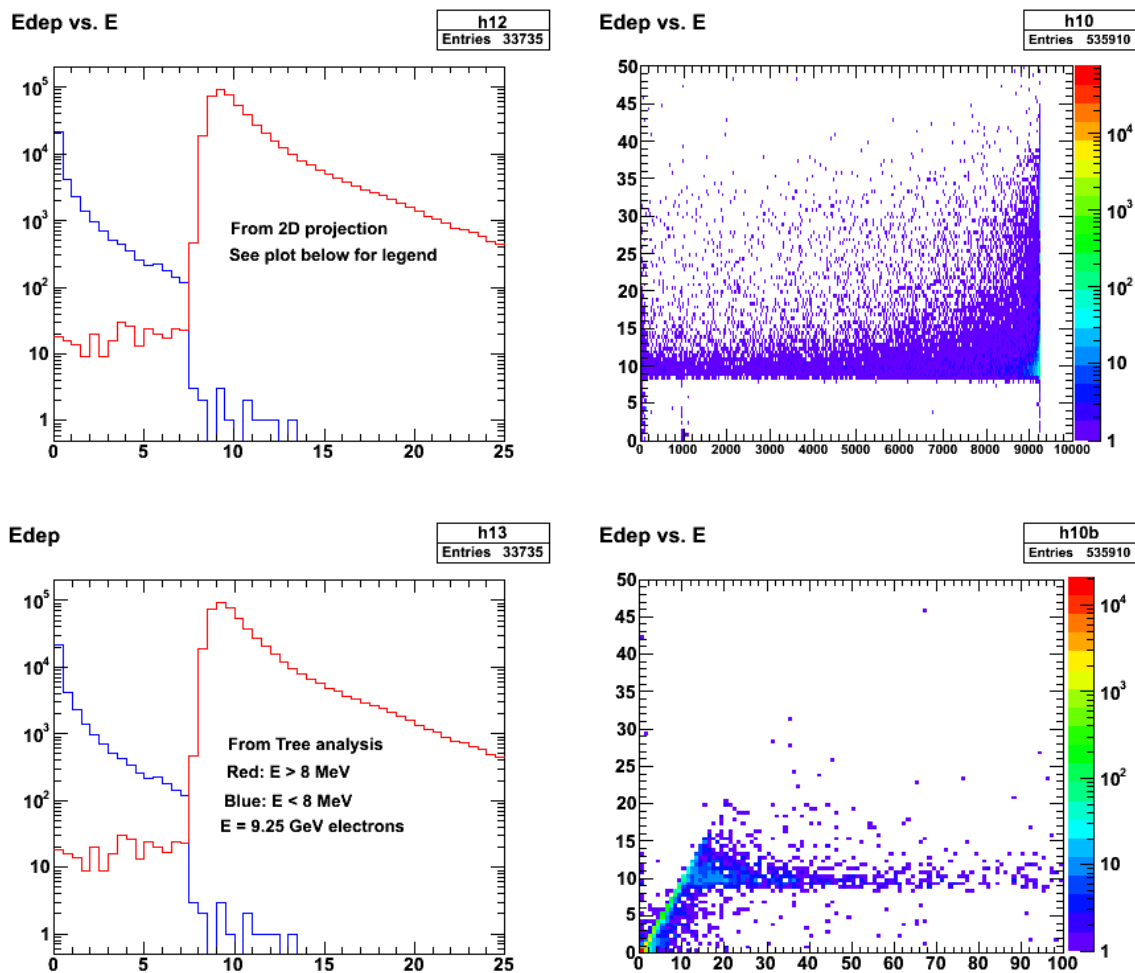

Fig 7. Plots of p1a for Edep determined two ways (left-hand panels) and the Edep vs. E plot at large and small scales (right-hand panels).

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root tree file) you uploaded.

Now do the same analysis with incident electron energy of 3.5 GeV which is near the quasielastic electron energy at the large-angle edge of p1a. For Edep we get almost exactly the same thing.

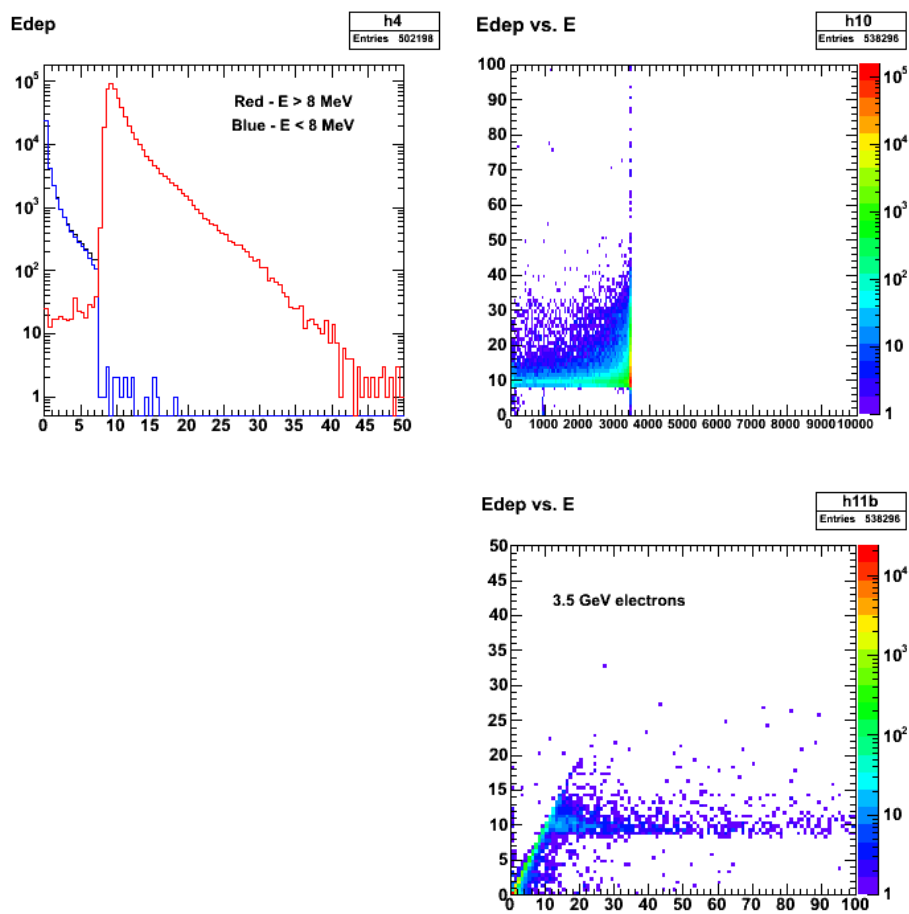

Fig 8. Plots of p1a for Edep and the Edep vs. E plot at large and small scales (right-hand panels).

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root tree file) you uploaded.

Now do panel 3.5 GeV p1b.

```
gmc -USE_QT=0 -OUTPUT="evio, mipstest.ev" -N=500000 -PRINT_EVENT=20000 -HALL_MATERIAL=Vacuum -gcard=p1b.gcard -USE_PHYSICSL=gmc -BEAM_P="e-,3.5*GeV, 2!
```

Jerry Gilfoyle's Enotebook page 382 - Energy deposited info (for neutrons in p1a) (gpg)

[Modified Sun Jul 24 00:23:29 2011 (GMT) gpg]

Now do the same analysis as entry 380 for the neutrons. Fig 1 below shows the distributions of gmc E and Edep for neutrons with $p_n = 2.25$ GeV/c fired at the center of the p1a panel at $\theta_n = 25$ deg so it strikes the scintillator at 90 deg. The 2D plot in the lower, left panel shows that most of the neutrons have the momentum they start with, but there is a mysterious peak at low E that we don't understand at this time. Perhaps these are neutrons knocked out by the primary neutron??

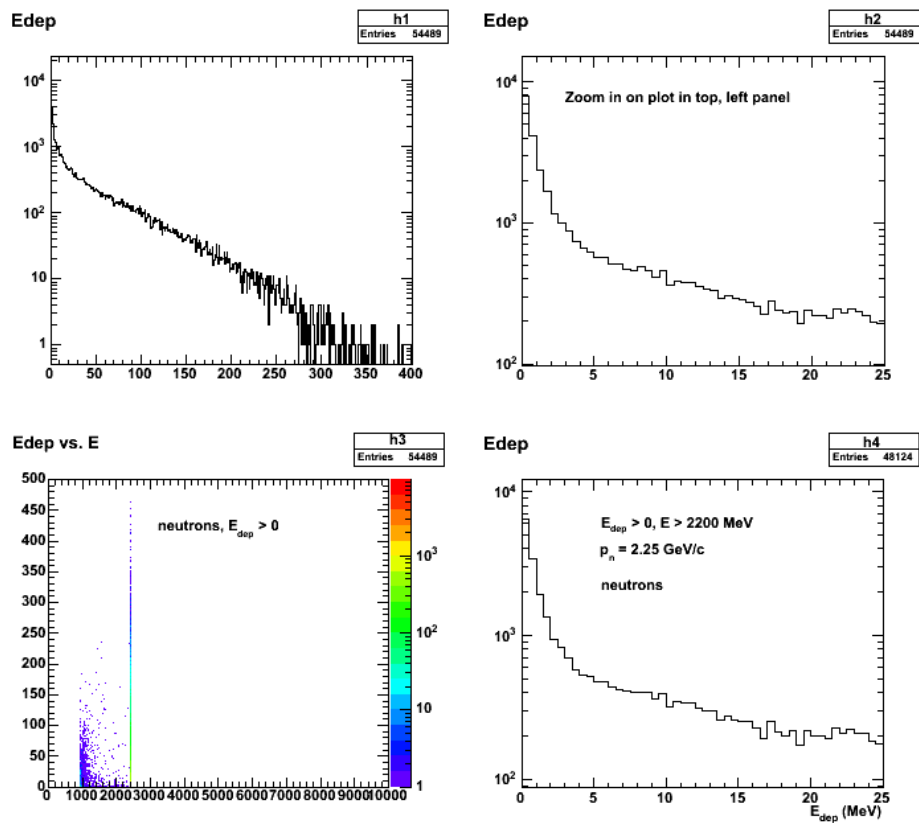

Fig 1. Plots for neutrons.

Click [here](#) to view the object (Root macro) you uploaded.

There is a sharp cutoff in the neutron energy in the top, right panel of Fig 2??? Dumb ass! This is the relativistic energy so the minimum is the neutron mass.

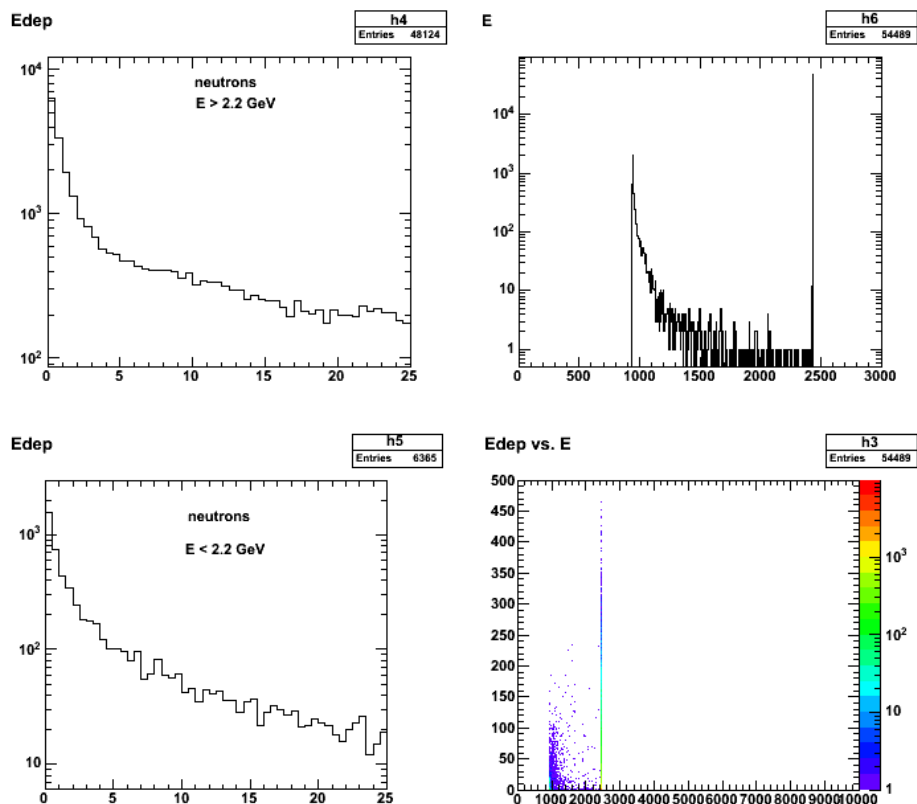

Fig 2. More neutron plots.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root ntuple file) you uploaded.

Now raise the incident neutron momentum. The neutron momenta above is close to the lower limit of the expected quasielastic neutron momentum for GMn12 and 9 GeV is close to the maximum.

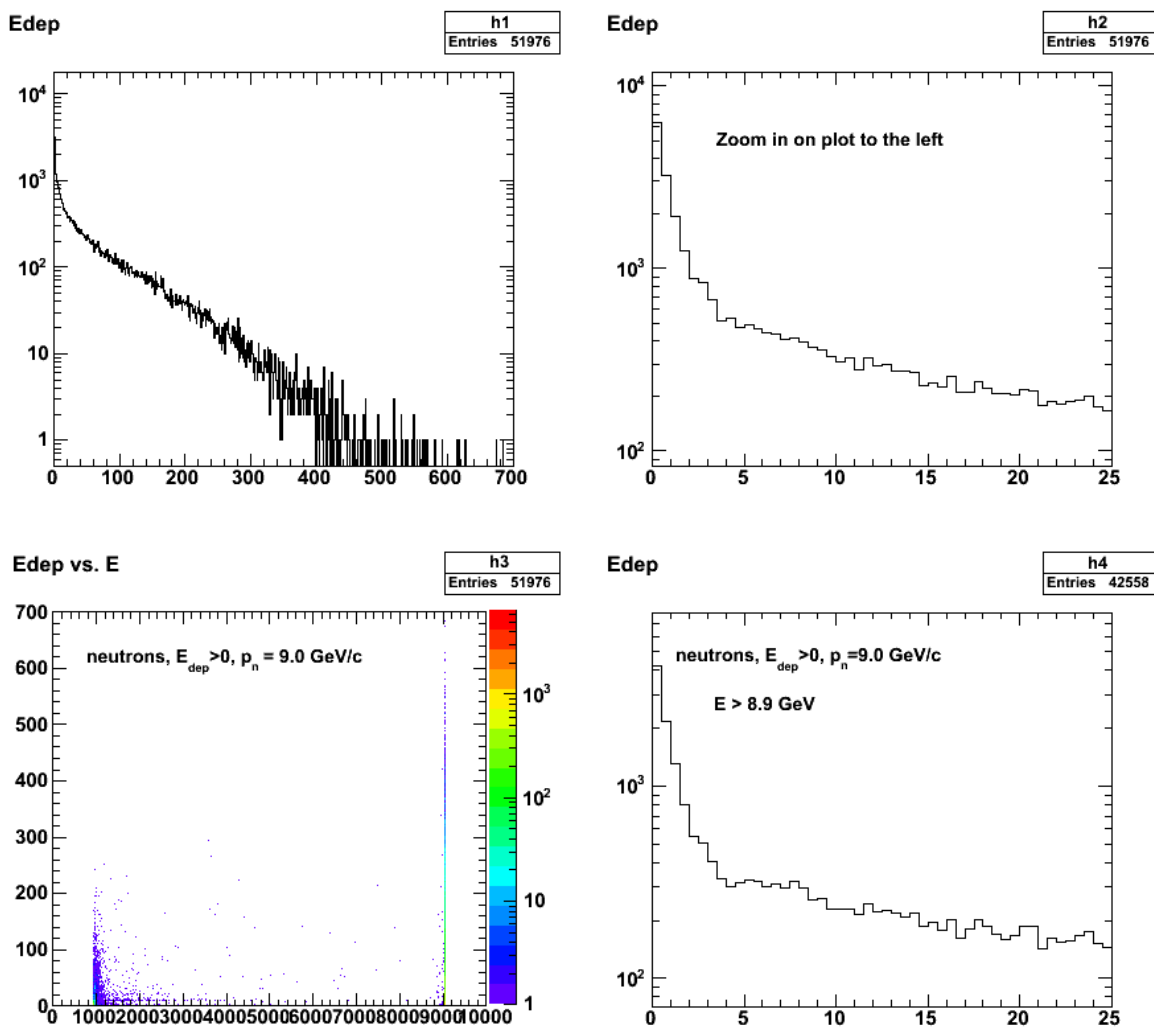

Fig 3. Same as fig 1 with $p_n = 9$ GeV/c.

Click [here](#) to view the object (Root macro) you uploaded.

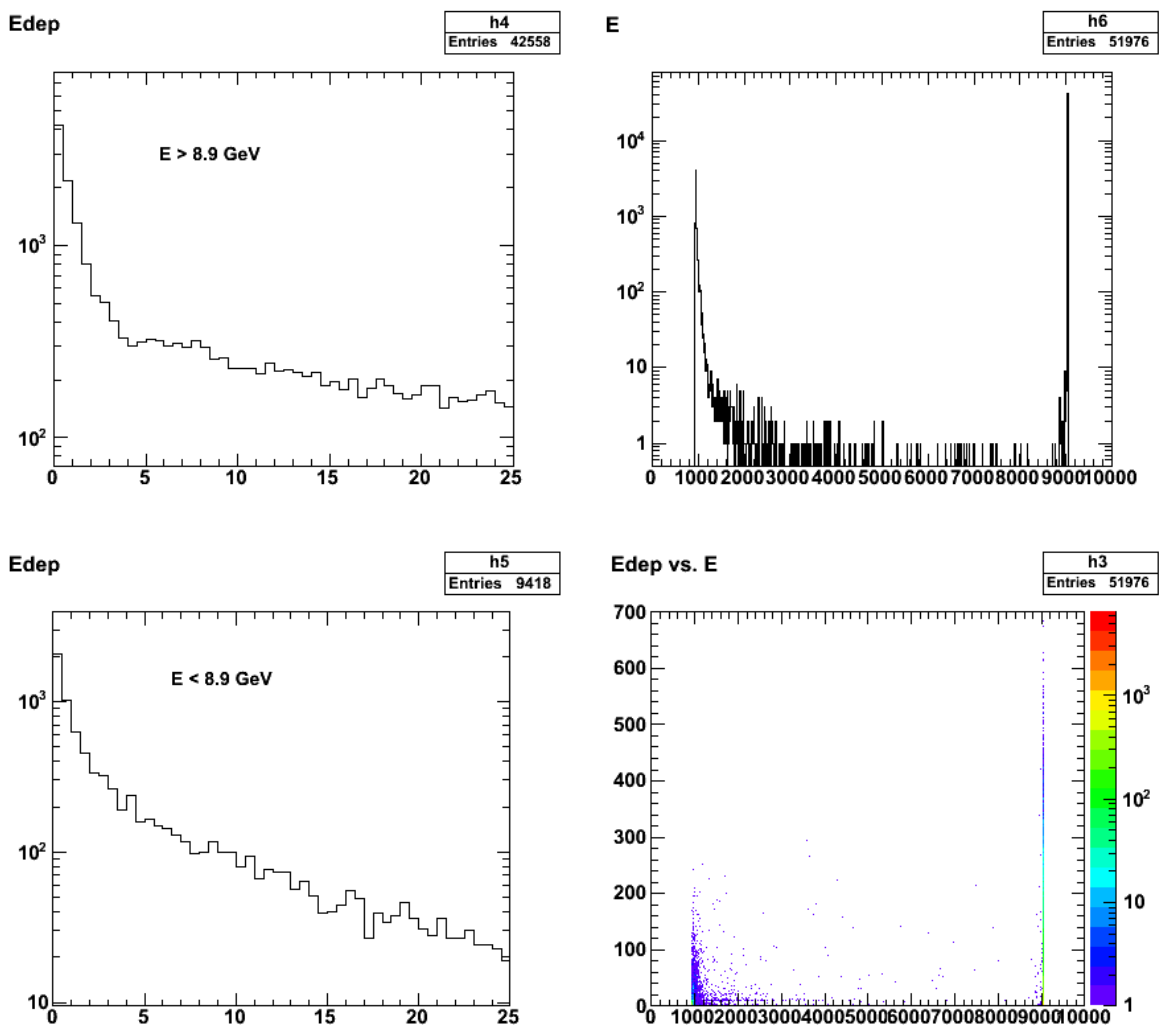

Fig 4. Same as Fig 2 for $p_n = 9 \text{ GeV}/c$.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root ntuple file with -N=500000) you uploaded.

For $p_n = 9 \text{ GeV}/c$ break down the Edep spectrum into its constituent parts. The spectrum is dominated by the high-momentum neutrons with some and low-E contributions from photons and pions.

Fig 5. Breakdown of the contributions to the Edep spectrum for $pn=9 \text{ GeV/c}$.

Click [here](#) to view the object (Root macro) you uploaded.

Some numbers from the Edep spectrum.

particle	PDG ID	N
protons	2212	4848
photons	22	20700
electrons	11	3619
positrons	-11	1939
anti-protons	-2212	0
anti-neutrons	-2112	0
π^0	111	138
π^+	211	4284
π^-	-211	5541
neutrons	2112	51976
all	-	99595

The number of thrown neutrons used to get the results above is 500,000 so $NDE = 51976/500000 = 0.104 \pm 0.005$

Now get rid of the weird spikes like the one in the upper, left plot in the figure below. They are associated with the pion events. There are spikes at the n^0 and $\pi^{+/-}$ masses. Excluding them gets rid of the spikes. See logfile log-11-07-19 for commands. The bump at about 10 MeV in Edep is from minimum ionizing pions (see the Edep vs. Eplot at lower left below). The events with Edep less than minimum ionizing are likely from low-energy pions that stop in the scintillator, but their distribution looks pretty random at low-Edep and low-E.

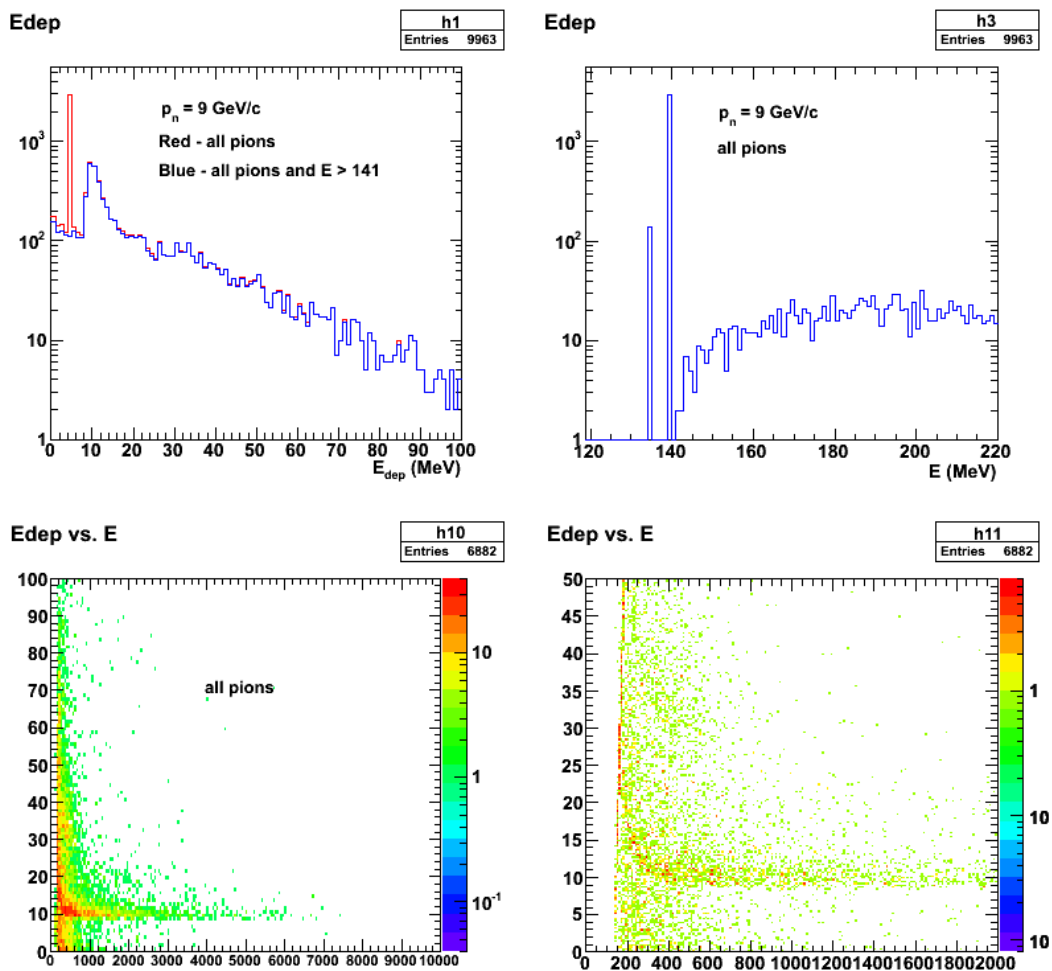

Fig 6. Pion production from neutrons.

Click [here](#) to view the object (Root macro) you uploaded.

Redo Fig 5 without the spikes.

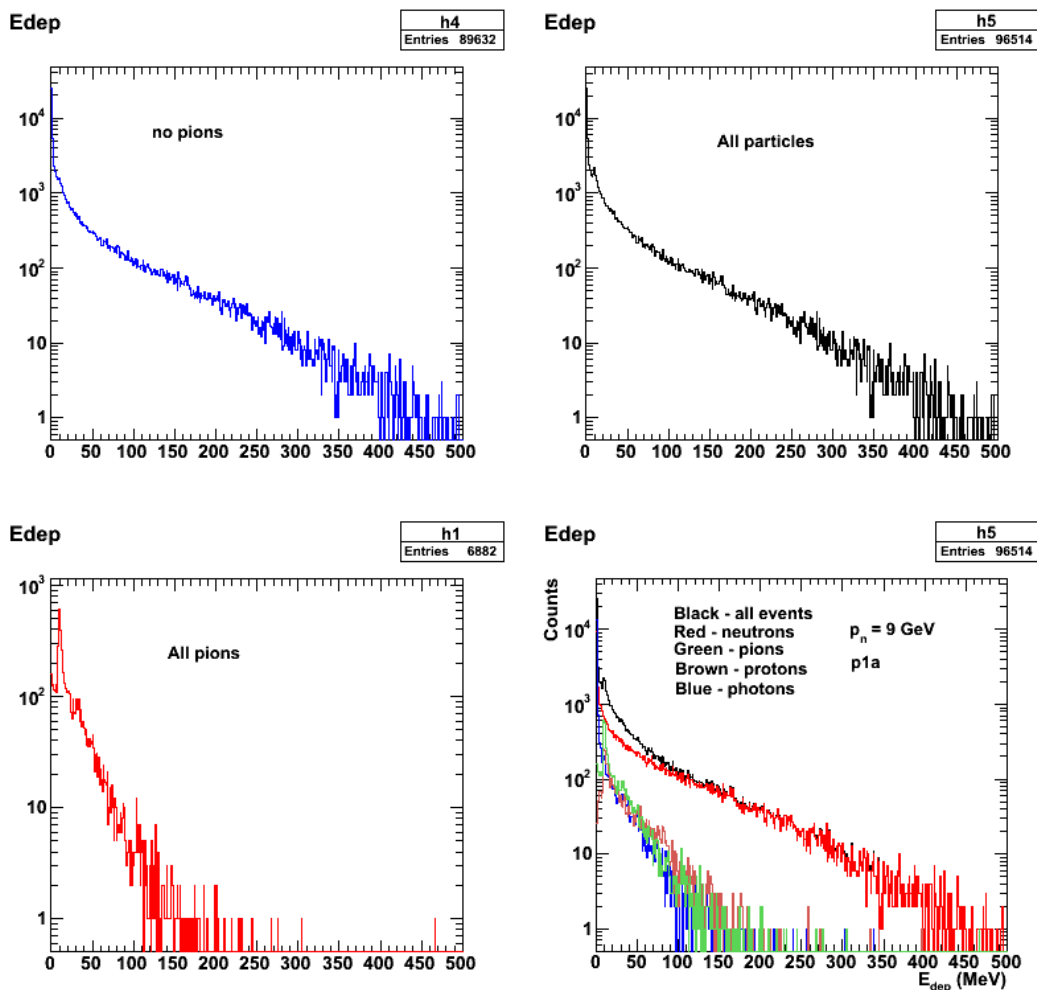

Fig 7. Redo Fig 5 without the spikes and plot some related spectra.

Aarrghh! FORGOT TO SAME STUFF!!!!

2011-07-20 21:14:04

Fig 8. Redo lower, right panel of Fig 7 for CLAS-Note.

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root tree file) you uploaded.

2011-07-20 21:23:10

Fig 10. Plot of Edep and Edep vs. E for p1a and pn=9.0 GeV/c neutrons.

Click [here](#) to view the object (Root macro) you uploaded.

Now do pn = 3 GeV which corresponds to forward-angle electrons. Note also that we want to do just neutrals in the spectra so leave out protons, $\pi^{+/-}$.

2011-07-23 13:39:35

Fig 11. Edep for pn=3 GeV.

Jerry Gilfoyle's Enotebook page 383 - P1A Neutron Energy Deposited Study (Mark Moog)

[Modified Sun Jul 24 00:55:32 2011 (GMT) Mark Moog]

We want to understand the energy deposited distribution for electrons and neutrons going through the forward time of flight panels. The neutron detection efficiency of these panels is highly dependent on the energy deposited cut we put on hits in these panels, so understanding the energy deposited distribution is very important. To study the distribution we simulate electrons and neutrons traveling perpendicular to each panel through its center. To distinguish between different phenomena in the distribution we shoot electrons or neutrons of a single energy at one time. We decided to "bracket" the energy range electrons and neutrons will have, choosing to show the energy deposited distribution for the lowest energy electron or neutron that would travel through the panel due to quasi-elastic electron-neutron scattering, as well as the highest.

The plots below show the results of shooting 3GeV neutrons at p1a. This is the lower end of the neutron energy which will go through the panel due to elastic electron-neutron scattering. The peak in energy deposited is due to pions and is studied in more detail in a later entry.

Click [here](#) to view the object (root macro) you uploaded.

In the plots above there is a spike in energy deposited at about 4MeV. This spike is due to Pi^+ and Pi^- particles, and is currently not understood. There is also a peak in energy deposited around 10MeV. This is the minimum ionizing peak. In the energy plot there is a sharp spike at 3GeV, these are the neutrons we created. There are also spikes at other non-zero points corresponding to the rest mass of various particles.

The plots below show the results of shooting 8GeV neutrons at p1a. This is the upper end of the neutron energy which will go through the panel due to elastic electron-neutron scattering. The peak in energy deposited is due to pions and is studied in more detail in a later entry.

Click [here](#) to view the object (root macro) you uploaded.

In the plots above there is a spike in energy deposited at about 4MeV. This spike is due to Pi+ and Pi- particles, and is currently not understood. There is also a peak in energy deposited around 10MeV. This is the minimum ionizing peak, and it is more pronounced than when lower energy neutrons were used (since higher energy neutrons make more particles.) In the energy plot there is a sharp spike at 8GeV, these are the neutrons we created. There are also spikes at other non-zero points corresponding to the rest mass of various particles.

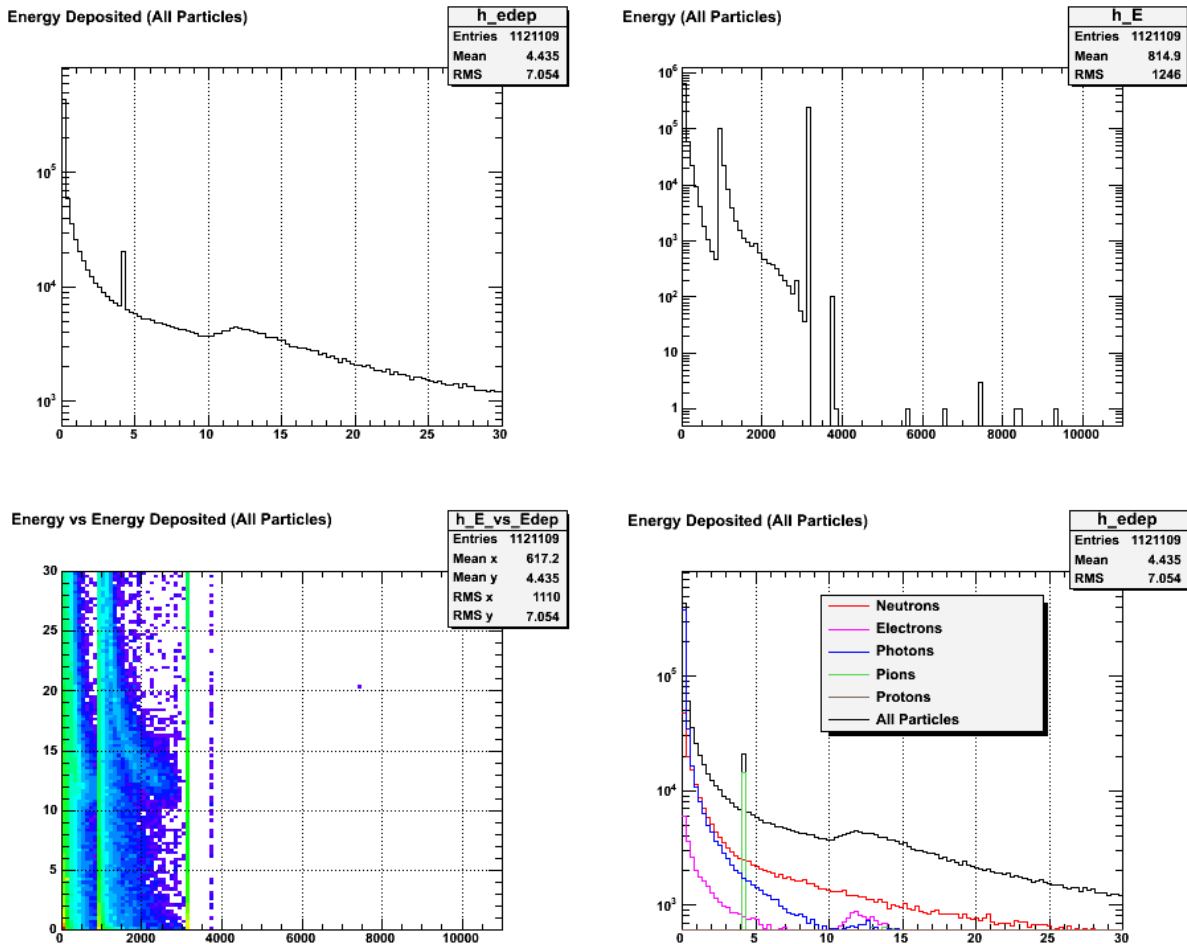

NOTE The final plots used for the neutron study of panel P1A are in the previous entry.

Jerry Gilfoyle's Enotebook page 384 - P1B Neutron Energy Deposited Study (Mark Moog)

[Modified Sun Jul 24 03:53:09 2011 (GMT) Mark Moog]

We want to understand the energy deposited distribution for electrons and neutrons going through the forward time of flight panels. The neutron detection efficiency of these panels is highly dependent on the energy deposited cut we put on hits in these panels, so understanding the energy deposited distribution is very important. To study the distribution we simulate electrons and neutrons traveling perpendicular to each panel through its center. To distinguish between different phenomena in the distribution we shoot electrons or neutrons of a single energy at one time. We decided to "bracket" the energy range electrons and neutrons will have, choosing to show the energy deposited distribution for the lowest energy electron or neutron that would travel through the panel due to quasi-elastic electron-neutron scattering, as well as the highest.

The plots below show the results of shooting 3GeV neutrons at p1b. This is the lower end of the neutron energy which will go through the panel due to elastic electron-neutron scattering. The peak in energy deposited is due to pions and is studied in more detail in a later entry.

Click [here](#) to view the object (root macro) you uploaded.

In the plots above there is a spike in energy deposited at about 4MeV. This spike is due to Pi^+ and Pi^- particles, and is currently not understood. There is also a peak in energy deposited around 12MeV. This is the minimum ionizing peak, and it is a few MeV higher than the MIP in P1A since P1B is thicker. In the energy plot there is a sharp spike at 3GeV, these are the neutrons we created. There are also spikes at other non-zero points corresponding to the rest mass of various particles.

The plots below show the results of shooting 8GeV neutrons at p1b. This is the upper end of the neutron energy which will go through the panel due to elastic electron-neutron scattering. The peak in energy deposited is due to pions and is studied in more detail in a later entry.

Click [here](#) to view the object (root macro) you uploaded.

In the plots above there is a spike in energy deposited at about 4MeV. This spike is due to P^+ and P^- particles, and is currently not understood. Jerry Gilfoyle's Enotebook page 385 - P2B Neutron Energy Deposited Study (Mark Moog)

[Modified Mon Jul 25 02:57:03 2011 (GMT) Mark Moog]

We want to understand the energy deposited distribution for electrons and neutrons going through the forward time of flight panels. The neutron detection efficiency of these panels is highly dependent on the energy deposited cut we put on hits in these panels, so understanding the energy deposited distribution is very important. To study the distribution we simulate electrons and neutrons traveling perpendicular to each panel through its center. To distinguish between different phenomena in the distribution we shoot electrons or neutrons of a single energy at one time. We decided to "bracket" the energy range electrons and neutrons will have, choosing to show the energy deposited distribution for the lowest energy electron or neutron that would travel through the panel due to quasi-elastic electron-neutron scattering, as well as the highest.

The plots below show 2.4GeV neutrons shot at P2B. Since P2B is much smaller than P1A and P1B, a much smaller range of neutron momenta travel through it, so we only simulated one momentum. We had to move the event vertex up 213.7cm in the z direction and shoot at an angle of 58.8 degrees to be perpendicular to p2b.

Click [here](#) to view the object (root tree file) you uploaded.

In the plots above there is a spike in energy deposited at about 4MeV. This spike is due to Pi^+ and Pi^- particles, and is currently not understood. There is also a peak in energy deposited around 10MeV. This is the minimum ionizing peak, and it is barely visible since 2.4GeV neutrons don't create many other particles (and the MIP is caused by non-neutron particles.) In the energy plot there is a sharp spike at 2.4GeV, these are the neutrons we created. There are also spikes at other non-zero points corresponding to the rest mass of various particles.

Plots for the CLAS-Note.

Jerry Gilfoyle's Enotebook page 386 - Pions in P2B (Mark Moog)

[Modified Wed Jul 20 21:19:59 2011 (GMT) Mark Moog]

We want to explain the mysterious peak of 4MeV in the energy deposited plot seen in previous entries ([here](#), [here](#), and [here](#)). This peak is caused by pions so we will take a closer look at how they are interacting with the forward time of flights. In the plots below we can see two spikes in the energy plot. One at the Pi^0 rest mass, and one at the Pi^+/Pi^- rest mass. Looking at the Energy vs Energy Deposited plot and zooming in on the mysterious 4MeV spike we can see that it is due almost entirely to the Pi^+ and Pi^- particles.

Energy Deposited (All Pions)

Energy (Pion)

Energy vs Energy Deposited (Pion)

Energy Deposited (All Pions)

To see if the spikes at the Pi^0 and Pi^+/Pi^- rest masses are actually spikes, and not very tight distributions, we zoom in on those energies. As you can see these are not tight distributions, they really are spikes.

zoomed in on pi0 rest mass

zoomed in on pi+ rest mass

Jerry Gilfoyle's Enotebook page 387 - Pi0 vs Pi+ Study (Mark Moog)

[Modified Sat Jul 23 16:59:50 2011 (GMT) Mark Moog]

We want to explain the mysterious peak of 4MeV in the energy deposited plots of forward time of flight panels seen in previous entries ([here](#), [here](#), and [here](#)). This peak is caused by pions, and we took a closer look at them [here](#). We saw both Pi0 and Pi+/Pi- in the plots, so now we will separate them and look at their individual contributions.

First we will look at the Pi0s. These particles decay into two photons in 10^{-17} seconds (virtually immediately.) they should have no time to deposit energy, and yet some of them are depositing over 100MeV in P2B!

Energy Deposited (Pi0)

2011-07-20 16:05:55

The fact that Pi0s are depositing energy in P2B seems even stranger when you look at the Pi0 energy distribution. They all have an energy of their rest mass, and thus have no kinetic energy, so how can they deposit energy in P2B?

Energy (Pi0)

2011-07-20 16:05:38

Since their energy plot is just a spike at the rest mass, the energy vs energy deposited plot contains little additional info.

Energy vs Energy Deposited (Pi0)

2011-07-20 16:07:58

When we zoom in to the energy vs. energy deposited graph for Pi0 we can see that there is no spike at 4MeV. This spike must be due to just Pi+ and Pi-.

Energy vs Energy Deposited (Pi0)

2011-07-20 16:04:43

Looking at Pi+/Pi- energy deposited we can see some interesting features. First there is the 4MeV mystery spike. Then there is the minimum ionizing peak at 10MeV. Also notice that there are about 20 times more Pi+/Pi- than Pi0.

Energy Deposited (Pi+-)

2011-07-20 16:06:41

For the Pi+/Pi- energy plot we can see the rest mass spike, along with a small distribution that peaks at 190MeV. This distribution probably contains the pions that make sense, but we still need to understand the rest mass spike.

Energy (Pi+-)

2011-07-20 16:05:24

Below is a very interesting plot. We can see the rest mass spike, but we can also see a diagonal line of "stopped" pions. This diagonal line is created by pions which are stopped by the time of flight scintillator and deposit all of their kinetic energy. Any point above this diagonal corresponds to pions which deposit more than their kinetic energy (which seems strange.) Most pions are below this line, and these are pions which pass all the way through the scintillator. The rest mass spike is entirely above the diagonal (obviously.)

Energy vs Energy Deposited (Pi+-)

2011-07-20 16:08:51

Zooming in on the rest mass spike near the 4MeV mystery spike we see something interesting. The "stopped" pion diagonal doesn't start at (rest mass, 0) like one would assume, but instead starts around (rest mass + ~3, ~3). This probably means the minimum amount of energy a pion deposits in one step is 3MeV. If it was 4MeV then we might have an explanation of the mystery spike! but it isn't....

Actually looking at the plot again, I would say that the diagonal does go all the way to (rest mass,0) but we don't have good enough statistics to fill it in. There

are many pions in the area around (rest mass, 0), just none connecting it to (rest mass + ~3, ~3) due to poor statistics.

Energy vs Energy Deposited (Pi+-)

2011-07-20 16:03:50

Jerry Gilfoyle's Enotebook page 388 - Generated Momentum and Theta Momentum Deltas (Mark Moog)

[Modified Tue Aug 2 17:58:45 2011 (GMT) Mark Moog]

Reconstruction isn't perfect, and we don't want to include poorly reconstructed events in our neutron detection efficiency calculation. To exclude poorly reconstructed events we can put a cut on the percentage difference of reconstructed and generated electron momentum. However, during an actual experiment we won't have access to the 'generated' electron momentum. Instead of using the generated electron momentum we will use the momentum calculated from the electron's theta scattering angle instead. This "from theta" momentum is the momentum the electron should have if it scatters elastically off a neutron at 11GeV at the reconstructed angle. This is a good replacement for generated electron momentum since the scattering angle is reconstructed very accurately.

below next to each plot is the log scale version with more bins.

(delta p) / p between "from theta" and generated momentum

2011-07

Above the plot compares the percentage difference between the "from theta" electron momentum and the generated electron momentum. They are very close together, mostly within a couple of percent. However there is a lump at about 12% that I will look into further. I believe it is do to poor electron angle reconstruction at very small angles...

Jerry Gilfoyle's Enotebook page 389 - Gamma vs Energy Deposited Plots (Mark Moog)

[Modified Tue Jul 26 21:47:13 2011 (GMT) Mark Moog]

Below I have some gamma vs. energy deposited plots for quasielastic electron-neutron scattering at 11GeV over a large range of scattering angles (4-45 degrees). They are exactly what one would expect after studying gamma and energy deposited separately. There is no interesting dependency between the two.

In this first plot you can see the electrons at about .8 radians and the neutrons around 0 radians as expected

Gamma vs Energy Deposited (All Panels)

2011-07-26 14:50:35

This plot contains all particles, both charged and neutral.

this is the same plot as above, but zoomed in onto the neutron gamma range

Gamma vs Energy Deposited (All Panels)

2011-07-26 14:55:21

This plot contains all particles, both charged and neutral.

Finally I have the neutron detection efficiency at different combinations of energy deposited and gamma cuts. If the energy deposited cut is set to 0MeV and the gamma cut is set to .17 radians (about 10 degrees) I get a neutron detection efficiency of 17.3% +/- 0.1

Jerry Gilfoyle's Enotebook page 391 - Momentum Resolution (Mark Moog)

[Modified Thu Aug 4 20:14:58 2011 (GMT) Mark Moog]

Below we show the difference in momentum resolution between low momentum electrons and high momentum electrons in quasi-elastic electron neutron scattering. The low momentum plots are for all electrons with a reconstructed momentum below 6GeV while the high momentum plots are for all other electrons. We show $(\Delta p)/p$ for both generated - reconstructed and "from theta" - reconstructed deltas. There is a large difference in resolution between low momentum and high momentum electrons. This is probably due to the fact that Socrat doesn't include energy loss in its reconstruction of electron momentum, and energy loss has a much greater effect on low momentum electrons; they lose a larger fraction of their energy.

Jerry Gilfoyle's Enotebook page 392 - Edep threshold effect on NDE (gpg)

[Modified Sat Aug 6 21:27:55 2011 (GMT) gpg]

Get the Edep threshold first.

1. Use Fig 3.3 in Costy's thesis.
2. low edge of MIP peak is at 7 MeV in gemc simulation.
3. Low edge of MIP peak is at 13.5 mm from zero in Fig 3.3 of Costy's thesis. His units are ADC channel so use gemc sim to set the scale.
4. For threshold = 20 mV (used for production running), the lower limit on the Edep spectrum is 1 mm.
5. Therefore Edep > (1/13.5)*(7 MeV) = 0.52 MeV

Fig 1. Dependence of NDE on changes to the Edep threshold. Raw data are below.

Jerry Gilfoyle's Enotebook page 393 - How I run NDE calculations (Mark Moog)

[Modified Fri Aug 5 19:22:16 2011 (GMT) Mark Moog]

Here I will take you through the process of running NDE calculations using my event generator, gemc, Socrat, and my analysis code

The first step is to use a perl script I call submit_nde.pl. This basically takes another script called bSubmit, and sends it out to the nodes of the cluster. bSubmit then runs a series of programs to simulate quaielastic electron-neutron scattering and sends the results back to the head node. Submit_nde.pl contains variable:

num_jobs -- the number of jobs you want to submit (how many cores do you want to use)

events_per_job -- which is the number of events per job you submit. The total number of events simulated is num_jobs * events_per_job

theta_min -- the minimum theta angle an electron should have in the simulation. Since angle and momentum are related, this also effects the maximum momentum an electron will have

theta_spread -- the spread past the minimum angle over which electrons will scatter

Ebeam -- keep this at 11.0GeV

[here is submit_nde.pl](#)

submit_nde.pl copies the content of bSubmit.sh to a new file and enters the variables such as events_per_job and theta_min into the new file. this file is then submitted to a node and executed. The contents of the bSubmit.sh file are as follows

The first section of the file are variables which are used in the simulation. The important part of bSubmit is the sequence of code it executes at the end

Step 1: nElasticEventGenerator -- this generates quaielastic e(n) events to feed into gemc

Step 2: gemc --simulate the events in the detector

Step 3: evio2root -- convert gemc's output from evio to root

Step 4: Socrat -- reconstruct electrons and enter important neutron reconstruction info into a root file

After Socrat runs its output is transfered back to the head node where I run my final analysis code.

[here is bSubmit.sh](#)

Finally I run my analysis code. This consists of three components:

analyze.C -- this is the only code you should run directly. It sets the values for many variables used throughout the analysis and calls other routines. It is a root program and should be executed using the command 'root -xb analyze.C++'

neutronTracking.h and neutronTracking.C -- these files were generated automatically with root to loop through the events in the neutronTracking tree, and were then modified for NDE alaysis. They calculate the NDE for each panel, as well as total NDE and create a bunch of initial histograms in a file called hist.root. Tweaking the NDE calculations should be done here.

createHists.C -- this code manipulates the initial histograms to create the final histograms you would want.

Click [here](#) to view the object (analyze.C) you uploaded.

Jerry Gilfoyle's Enotebook page 394 - No P1B NDE (gpg)

[Modified Mon Aug 8 11:56:12 2011 (GMT) gpg]

To test the accuracy of gmc and geant4 we ran the CLAS12 simulation for elastic neutron scattering with the P1B panel removed from the FTOF. This enables us to make a comparison with the E5 measurement of the NDE since the P1A and P2B panels are the same ones used in CLAS6. There is a dip at low neutron momentum (see Fig 1.) that is due to the small gap between the P1A and P2B panels. Fig 2. shows a neutron track that at `-BEAM_P="neutron,3.29*GeV, 35.0*deg, 0*deg"` that slips between the two FTOF panels. The gmc command is the following.

```
gmc -gcard=pla.gcard -DBHOST=quark.richmond.edu -DBUSER=clasuser -BEAM_P="neutron,3.29*GeV, 35.0*deg, 0*deg"
```

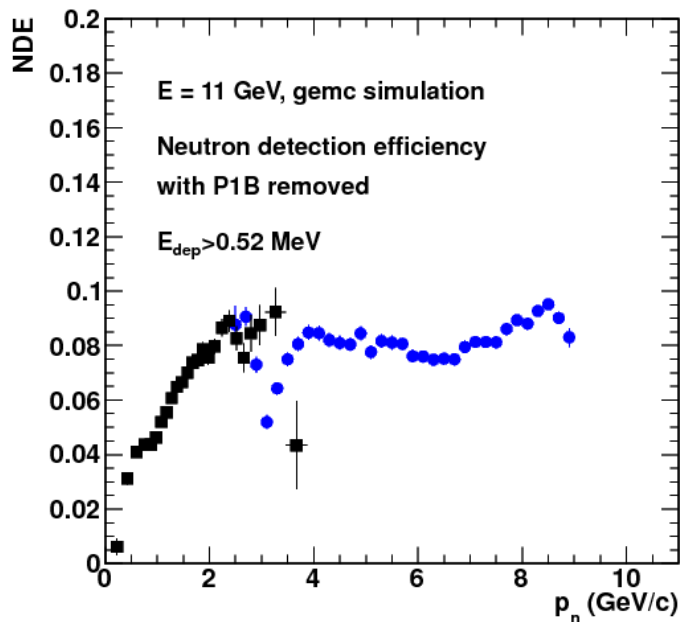

Fig 1. NDE for CLAS12 from gmc with panel P1B removed.

Click [here](#) to view the object (Root macro) you uploaded.

Fig 2. Neutron track from gemc showing $\theta_n=35^\circ$ track that does not strike either panel.

This gap will be covered by the new FTOF panel p1b.

Fig3. Same type of event as figure 2, but now the p1b panel is included to show the gap will be covered.

Jerry Gilfoyle's Enotebook page 395 - EC ADC (gpg)

[Modified Tue Aug 9 18:34:58 2011 (GMT) gpg]

The algorithm for turning deposited energy (Edep) in the EC and turning it into ADC channels was copied from gsim. Unfortunately, it looks like the value of the ADC is too small. See the two plots below.

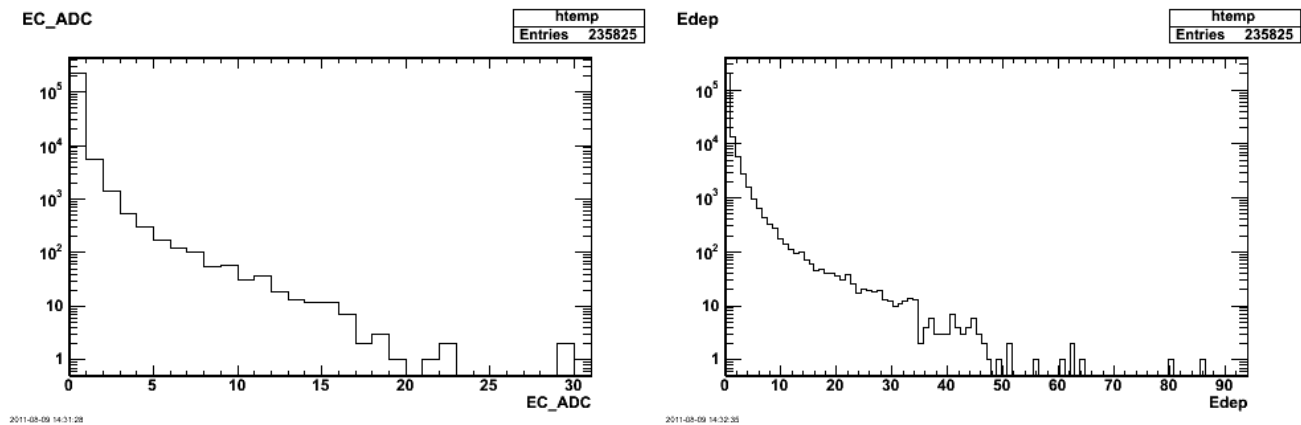

Fig 1. ADC histogram of the deposited energy for electrons (left-hand panel) and the histogram of the deposited energy (right-hand panel).

Jerry Gilfoyle's Enotebook page 396 - Update on CLAS12 EC sampling fraction (gpg)

[Modified Thu Aug 11 00:30:04 2011 (GMT) gpg]

Check and update the results for measuring the sampling fraction of the EC for CLAS12 using the gemc simulation.

1. CLAS6 results from EC NIM paper (NIM A460 (2001) 239-265) using GSIM.
2. Black curve in each plot based on ionization energy loss in materials preceding the EC.
3. Caveats: (1) electrons passed through different material, (2) \vec{B} field off in the CLAS12 simulation and \vec{B} field on in the CLAS6 simulation, (3) tracking used in CLAS6 simulation while Monte Carlo information used for CLAS12, (4) energy loss out the back, ...
4. Note different horizontal ranges.

gemc and GSIM sampling fractions are consistent to 10-15%.

Fig 1. Results shown at software meetings.

Jerry Gilfoyle's Enotebook page 397 - Check on final 2.6n ALTp (gpg)

[Modified Thu Aug 11 18:56:25 2011 (GMT) gpg]

In responding to BQ's questions on the CAN check that I get consistent results for ALTp at 2.6n.

Jerry Gilfoyle's Enotebook page 400 - W_{vo} study (gpg)

[Modified Tue Sep 20 22:07:33 2011 (GMT) gpg]

Try using WVO's formula for the residual mass in exclusive electron scattering to get at the QE events. His formula is the following with explanation from his email.

$$W_n = \sqrt{M_d^2 - 2 M_d E_p + m_n^2 + 2(M_d - E_p)\nu - Q^2 + 2|\vec{p}||\vec{q}|\cos\theta_{pq}}$$

Where M_d is the deuteron mass, m_n is the nucleon mass, E_p and $|\vec{p}|$ are the energy and momentum of the detected nucleon, ν is the energy transfer, Q^2 is the negative of the square of the four-momentum transfer and θ_{pq} is the angle between the detected nucleon and the three-momentum transfer. In an ideal world with no experimental complications, there would be a sharp peak at $W_n = m_n$ which would fall to zero and then start to rise at $W_n = m_n + m_{\pi}$. Once this is done, the question of whether you are in the quasielastic region, the dip region, etc. is determined by x . The expression you have used for W_n can be obtained by ignoring the binding energy of the deuteron using $M_d = 2 m_n$ and setting $p=0$. I have not examined your kinematics again to see if this is a good approximation, but it may be that using the correct expression would tighten things up a bit.

There are serious problems with my analysis below. The fix is finally reached for Figs. 14-15.

The plot below compares W and W_{vo} spectra for 2.6r. The main QE peak is significantly sharper for W_{vo} than W , but there appears to be more (???) background underneath the QE peak!

Fig 1. Comparison of W spectrum with W_{vo} .

Fig 8. Momentum distribution as a function of scattering angle of electrons (left-hand panel) and protons (right-hand panel) for the full 2.6r data set, deuterium target, and $W < 1.02$ GeV.

I tried changing the sign on the Q2 term for Wvo, but that didn't fix things. I should have known since at low E_p in Fig ?? Wvo looks correct; it is about the nucleon mass. At higher E_p or p_p , Wvo is too small which could be caused by the calibration for p_p making the momentum too large so that in the formula for Wvo, I subtract off too much. If this is true, if I look at the difference $p_p - p_{meas}$ where p_{meas} is the momentum from tracking and p_p is the momentum after corrections, then I should get a positive tail. What is more, if I plot p_p versus this difference, then the difference should increase with increasing p_p . Plot it and that is what I see.

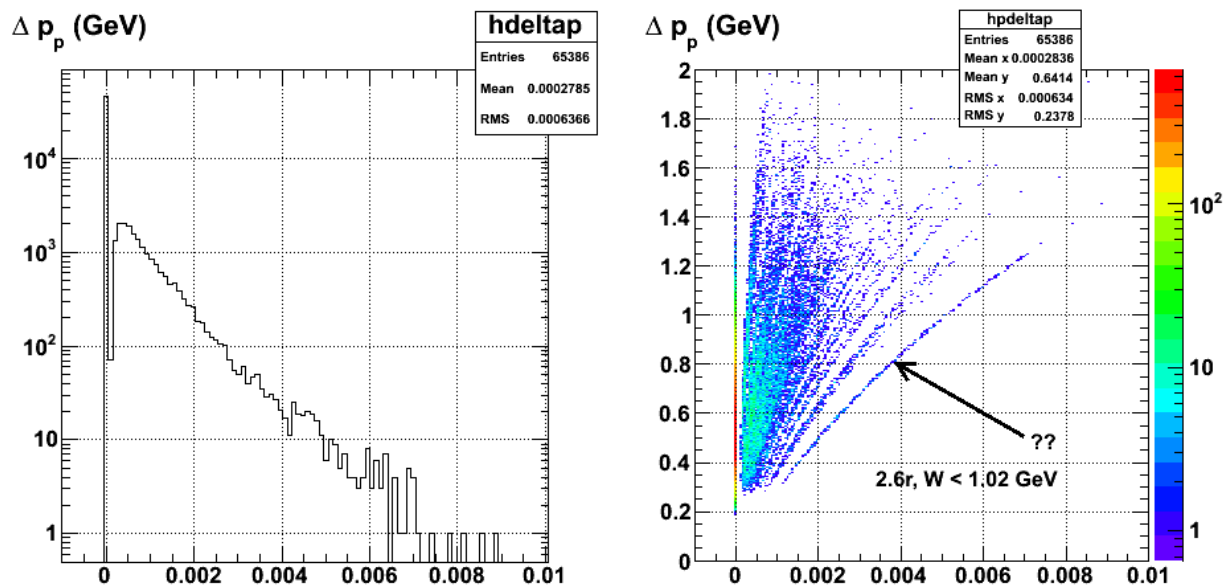

Fig 9. Plot of $\Delta p_p = p_{corr} - p[\text{proton}]$ (left-hand panel) and p_{corr} versus Δp_p (right-hand panel).

Click [here](#) to view the object (Root macro) you uploaded.

The mystery with the previous results is that p_p looks ok when compared with the elastic scattering curve in Fig. 8.

2011-08-25 17:39:47

Fig 10. Look at some timing quantities.

Adding the MM2 cut reduces the number of events by a third, but only trims out the edges of the accepted epn events. The large region at lower proton momentum well below the QE expectation is little effected. This is a problem!!!

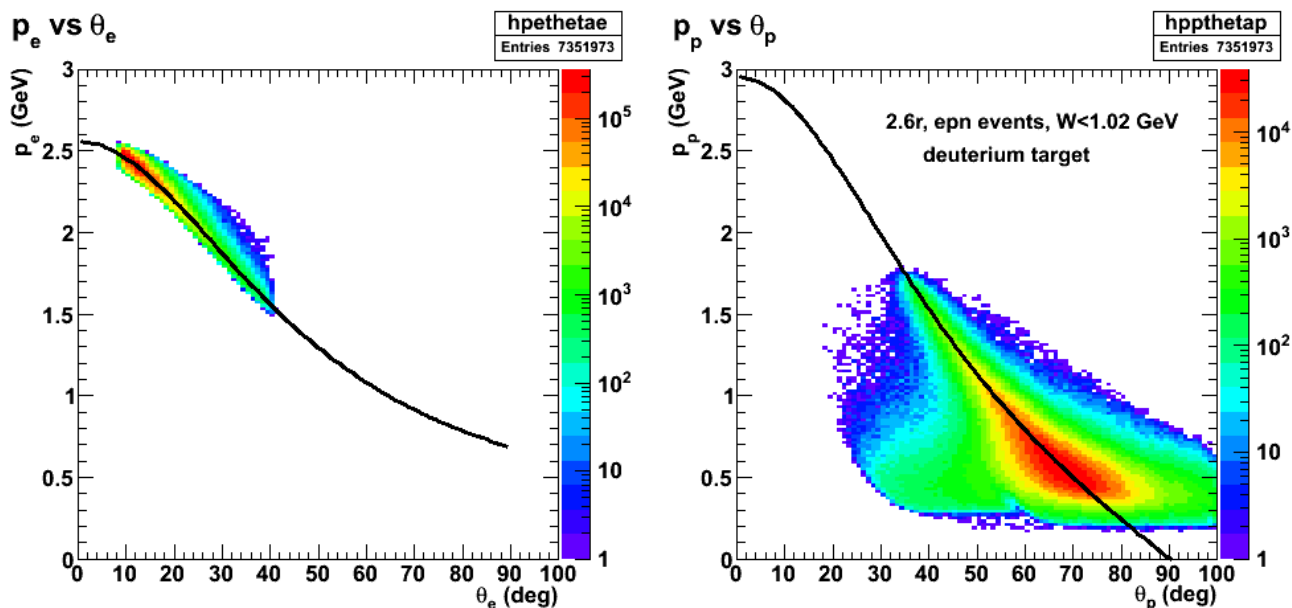

Fig 11. Momentum distribution as a function of scattering angle of electrons (left-hand panel) and protons (right-hand panel) for the full 2.6r data set, deuterium target, MM2 cut on neutron mass (epn events) and $W < 1.02$ GeV.

THE FIX Dumb ass me had a sign error in the calculation of the magnitude of the 3-momentum transfer. The correct equations are shown in the next figure. The 2D histogram of proton momentum p_p versus W_n/W_{vo} is in the following figure.

The mass of the residual left behind in the reaction $D(e, e'p)n$ is

$$W_n^2 = M_d^2 - 2M_d E_p + m_p^2 + 2(M_d - E_p)\nu - Q^2 + 2|\vec{p}_p||\vec{q}| \cos \theta_{pq} \quad (1)$$

where

$M_d = 1.876$ GeV is the deuteron mass,

$m_p = 0.93827$ GeV is the proton mass,

p_p is the measured proton momentum,

$E_p = \sqrt{p_p^2 + m_p^2}$ is the proton energy,

$\nu = E - E'$ is the energy transfer where E is the beam energy and E' is the measured scattered electron energy,

$Q^2 = 4EE' \sin^2 \frac{\theta}{2}$ is the square of the 4-momentum transfer where θ is the measured electron scattering angle,

$q = |\vec{q}| = \sqrt{Q^2 + \nu^2}$ is the 3-momentum transfer, and

θ_{pq} is the angle between the detected proton 3-momentum \vec{p}_p and the 3-momentum transfer \vec{q} .

Click [here](#) to view the object (Root macro) you uploaded.

Get the width of the Wvo QE peak. I will use this to set the upper limit on the Wvo cut to select QE events. The idea is that in the ideal world with perfect experimental resolution, the QE peak in Wvo would be a spike/Dirac delta function at the neutron mass. The measured width of the peak is then a measure of the experimental uncertainty. There should be no inelastic contributions to the QE peak until we reach the mass of the neutron + pion system. That limit ($0.939 \text{ GeV} + 0.139 \text{ GeV} = 1.078 \text{ GeV}$) will be smeared out by the experimental resolution. I will take the upper limit on the QE peak to be 3σ below the pion limit. The width of the peak below is about 0.02 GeV so the upper cut on Wvo will be $1.08 \text{ GeV} - 3 \times 0.02 \text{ GeV} = 1.02 \text{ GeV}$.

2011-08-31 17:16:06
Fig 20. Fit to the QE peak in the Wvo spectrum to get the W resolution for CLAS.

Click [here](#) to view the object (Root macro) you uploaded.

Now look at xBJ. WVO says we can put a cut here to select QE events. The results below are depressing. The xBJ spectrum using the Wvo QE selection cut has more counts, but is much wider than the previous method using the W+MM2 cuts.

Jerry Gilfoyle's Enotebook page 401 - 2D cut for QE events (gpg)

[Modified Tue Sep 20 21:44:13 2011 (GMT) gpg]

To select quasielastic events in $d(e,e'p)n$ we start with the definition of the residual mass left behind in the reaction, i.e. the mass of the neutron or whatever else is left behind. Note this is more than the usual W spectrum calculated solely from the electron information. The equation is (barring my mistakes in translation from WVO) the following.

The mass of the residual left behind in the reaction $D(e, e'p)n$ is

$$W_n^2 = M_d^2 - 2M_d E_p + m_p^2 + 2(M_d - E_p)\nu - Q^2 + 2|\vec{p}_p||\vec{q}| \cos \theta_{pq} \quad (1)$$

where

$M_d = 1.876$ GeV is the deuteron mass,

$m_p = 0.93827$ GeV is the proton mass,

p_p is the measured proton momentum,

$E_p = \sqrt{p_p^2 + m_p^2}$ is the proton energy,

$\nu = E - E'$ is the energy transfer where E is the beam energy and E' is the measured scattered electron energy,

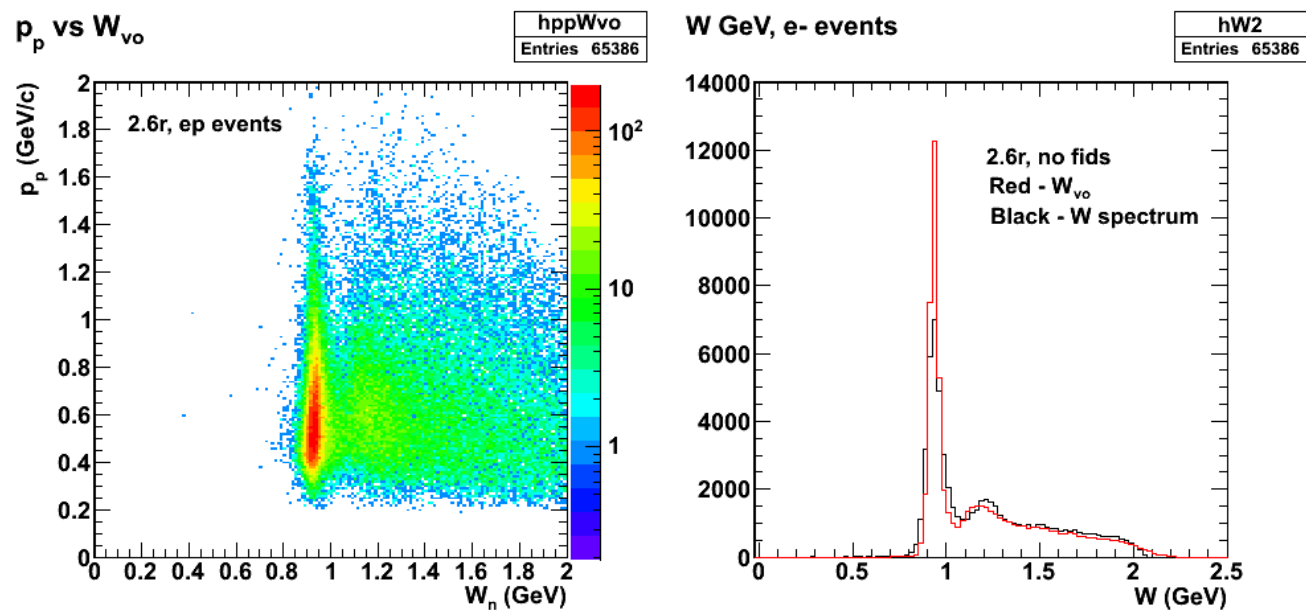

$Q^2 = 4EE' \sin^2 \frac{\theta}{2}$ is the square of the 4-momentum transfer where θ is the measured electron scattering angle,

$q = |\vec{q}| = \sqrt{Q^2 + \nu^2}$ is the 3-momentum transfer, and

θ_{pq} is the angle between the detected proton 3-momentum \vec{p}_p and the 3-momentum transfer \vec{q} .

Fig 1. Definition of W_n/W_{vo} with all the ingredients.

Now apply the equation for W_{vo} event-by-event to get the W_{vo} spectrum and compare it with the W spectrum calculated just with the electron information (right-hand panel in Fig. 2). The W_{vo} histogram (red) is narrower and there is a cleaner distinction between the QE events and higher energy transfer states like the resonances.

2011-08-30 22:26:56

Click [here](#) to view the object (Root macro) you uploaded.

2011-08-30 22:36:01

Click [here](#) to view the object (Root macro) you uploaded.

Fig 2. 2D plot of proton momentum vs W_{vo} (left) and comparison of W and W_{vo} spectra (right).

Now generate the Bjorken x distribution with a cut on Wvo. The position of the cut is determined, first, from the sum of the neutron mass plus pion mass (0.94 + 0.14 GeV). If we had perfect resolution in CLAS and we require $W_{vo} < 1.08$, then we should only have final states with a single neutron. Since we do have non-zero resolution in CLAS, I estimated that resolution from the width of the neutron peak in the Wvo spectrum. This would be an infinitely narrow spike without the CLAS resolution spreading it out. I got a width of $CLASres=0.03$ GeV so I put the Wvo cut to select neutrons in final state at the following.

$$W_{vo} < M_{proton} + M_{pion} - 2 * CLASres = 1.02 \text{ GeV.}$$

The resulting distribution of Bjorken x is shown below. I am happy to see a peak at $x=1$ which should be the position of the QE events. I am perplexed by the width of that peak and because it goes very far above and below the $x=1$ peak. We expect that for a deuteron target x could be as large as $x=2$, but the spectrum here goes well above that limit. What is pushing these events to high x??

2011-09-03 10:46:54

Fig 3. Spectrum of Bjorken x with $W_{vo} < 1.02$ GeV.

To attempt to understand what is going on with the x spectrum in the figure above try using a 2D cut in root on the p_p (proton momentum) versus θ_e (electron momentum) histogram to remove the weird events from the QE sample. Use the same method on the θ_e (electron momentum) versus θ_p (proton momentum) histogram. The plots are shown below. There is a clear QE ridge in both plots that coincides with a calculation of the momentum versus theta for elastic scattering of an electron off the proton (i.e. ignoring the Fermi motion of the nucleons in deuterium). What is the broad, flat background around the QE ridge? Radiative events? These events only make up 1-2% of the total, but get rid of them anyway by applying the two, 2-D cuts shown in the figure below and looking at Bjorken x again.

2011-09-20 16:30:09

2011-09-20 16:34:23

Click [here](#) to view the object (Root macro) you uploaded.

Click [here](#) to view the object (Root macro) you uploaded.

Fig 4. Plot showing the cuts on electrons (left) and protons (right).

The impact on Bjorken x of adding the cuts on the electron/proton p vs theta plots is shown below. The black curve is the raw x spectrum for e-p coincidences. The blue curve now has the $W_{vo} < 1.02$ GeV cut added so it is the same as Fig. 3. The red curve is x with $W_{vo} < 1.02$ GeV and that the electron and proton satisfy the 2D cuts shown in Fig. 4. The events at low x are reduced (good news), but there is no effect on the high-x events???

Fig 5. Effect of various cuts on the Bjorken x spectrum.

The number of events in the two distributions in Fig. 4 is different for the electron and proton events. They should be the same. Those two plots were generated at different times when I was futzing around with the cuts. Check them (see below) and they look ok.

Fig 6. Check on the number of events in the 2D histograms of momentum versus scattering angle for electrons and protons.

Click [here](#) to view the object (Root macro) you uploaded.

The next step would be to put a cut on Bjorken x at the top of the peak, but how do we select the cuts. For the previous analysis I set narrow cuts (by eye and arbitrarily) and then scanned over the peak to see how it effected ALTp. We need a better procedure to justify our choice.

Jerry Gilfoyle's Enotebook page 402 - Checking Target Cuts (gpg)

[Modified Sat Oct 1 21:35:15 2011 (GMT) gpg]

At LW's suggestion I will look to make sure that we are eliminating the target windows which could account for the XBJ>2 events in the xBJ spectrum in the previous entry. First plot below looks ok. If anything I can expand the target cut for deuterium.

Fig 1. v_z for 2.6r electrons with all the other cuts off.

Click [here](#) to view the object (Root macro) you uploaded.

Look at the target position with different cuts.

```
if (e_event &&
    target_walls_e &&
    good_electron_fiducial &&
    //quasielastic_cut &&
    good_egiyon_threshold &&
    good_EC_pion_threshold &&
    good_electron_EC_fiducial &&
    good_electron_EC_trk_coords_fiducial &&
    good_sampling_fraction &&
    good_photoelectrons
) {
```

Fig 2. \bar{I}_e vs. v_z for the above conditions.

Click [here](#) to view the object (Root macro) you uploaded.

Now turn off the electron fiducial cuts. The phi dependence is due to the electron beam not coming through in the center of CLAS at around 30 deg (according to Larry Weinstein).

```

if (ep_event &&
    target_walls_ep &&
    good_e_p_vertex &&
    //good_electron_fiducial &&
    //good_proton_fiducial &&
    //quasielastic_cut &&

As a check: same as figure 7 with fiducial cuts on. Almost everything went away.

2011-09-30 12:25:07

Fig 9. Same as fig 7 with fids on.

Click [here](#) to view the object (Root macro) you uploaded.

Now check the effect on ALTP. We turn ON the fids and use just the WVO cut and turn off the W+MM2 cut. The result is shown below. The depth of the dip is less, but the uncertainty has shrunk! This is presumably due to the fact that we are taking more events by integrating over the entire Bjorken x distribution. The shrinking of the dip needs to be studied with Wally to see how his calculation varies with x. The first result he sent for $x=1.25$ last week shows the depth shrinking. We will have to average over x and if the dip goes away then maybe we could put cuts on x_{Bj} . The standard ALTP does not agree with past results in entry 398, but the cuts for the deuterium target are different from the standard set.

Cuts for Fig 10 are:

```
if (ep_event &&
    target_walls_ep &&
    good_e_p_vertex &&
    good_electron_fiducial &&
    good_proton_fiducial &&
    good_Wvo_quasielastic_cut &&
    //good_xBj_cut &&
    //Q2cut &&
    good_egiyan_threshold &&
    good_EC_pion_threshold &&
    good_electron_EC_fiducial &&
    good_electron_EC_trk_coords_fiducial &&
    good_mass_p &&
    good_sampling_fraction &&
    good_photoelectrons) {
```

2011-10-01 04:07:51

Fig 10. Comparison of old ALTp with new one with $W_{vo} < 1.02$ GeV cut and fids on. RC calculations are on. Used the wrong deuterium target cut.

Click [here](#) to view the object (Root macro) you uploaded.

Reset the deuterium target cut to the default values and the comparison with the standard in entry 398 is close enough.

2011-10-01 17:31:28

Fig 11. Comparison of old ALTp with new one with $W_{vo} < 1.02$ GeV cut and fids on. RC calculations are on. Default deuterium target cut back in.

Jerry Gilfoyle's Enotebook page 403 - Comparing Missing Mass and W_{ν} (gpg)**[Modified Tue Oct 4 03:06:10 2011 (GMT) gpg]**

The missing mass and the residual mass from W_{ν} should be the same thing. I calculate them differently using the reconstructed 3-vectors to get the missing mass m_X from $d(e,e'p)X$. For W_{ν} I use the formula that Wally worked out (see entry 401). The plot below shows they are very close to one another, but still differ by 0.1% or 10^{-3} in the centroid and by about 4% in the RMS.

**Fig 1. Comparison of missing mass and W_{ν} from two different methods for 2.6r.**Click [here](#) to view the object (Root macro) you uploaded.

Jerry Gilfoyle's Enotebook page 404 - Questions on $x > 2$ events (gpg)

[Modified Thu Oct 6 10:51:20 2011 (GMT) gpg]

LW has asked why the fiducial cuts have such a dramatic effect on the Bjorken x distribution. Trying to answer him I generate a few plots. The first one below shows there is something funny about the $x > 2$ events where there is an overabundance of events in sector 3 relative to the other sectors. Misalignment effect? Beam not going down the center?

Fig 1. Electron ϕ versus v_z for 2.6r, fids off, $x > 2$.

Click [here](#) to view the object (Root macro) you uploaded.

Look at the same distribution for the proton.

Fig 2. Same as fig 1 for protons.

Click [here](#) to view the object (Root macro) you uploaded.

What does the missing mass distribution look like? It's all low mass ($MM2 < 0.88$ GeV2)!

2011-10-04 16:37:10
Fig 3. Mass distribution for $x>2$, $2.6r$, $W_n<1.02$ GeV.

Click [here](#) to view the object (Root macro) you uploaded.

2011-10-04 16:41:38
Fig 4. Same as Fig 3 for W_{vo} .

2011-10-04 17:14:32
Fig 5. Energy versus W_n for protons, $2.6r$, $x>2$, and $W_n<1.02$ GeV

Click [here](#) to view the object (Root macro) you uploaded.

Fig 6. Same as Fig 5 for proton momentum instead of energy.

Click [here](#) to view the object (Root macro) you uploaded.

The plot above shows the proton momentum is too small at increasing p_p . I should have a straight ridge for $W_n < 1.02$ GeV, but p_p is decreasing with decreasing W_n .

Now look at the electron.

Fig 7. Same as Fig 6 for electrons.

Click [here](#) to view the object (Root macro) you uploaded.

Turn off the $x > 2$ cuts and get the following. Where has the W_{vo} cut disappeared to??!! Dumb ASS! I filled the histogram outside the W_{vo} cut. I also turned off the fiducial cuts.

2011-10-04 19:04:51

Fig 8. Same as Fig 6 with Bjorken x cut turned off.

Jerry Gilfoyle's Enotebook page 405 - Checking on target configuration (gpg)

[Modified Sat Oct 15 17:31:33 2011 (GMT) gpg]

It looks like the parameters are too small for the target. Were the numbers in inches when they should have been converted to mm?

Fig 1. A geantino starting with vertex $x=y=z=0$.

Fig 2. A geantino with $x=6$ mm, $y=z=0$ and it should be inside the target.

Jerry Gilfoyle's Enotebook page 406 - Comparison with WVO calculations averaged over x for 2.6r. (gpg)

[Modified Sun Oct 16 19:26:06 2011 (GMT) gpg]

Wally has sent me calculations for $D(e,e'p)n$ at different Q^2 and Bjorken x so I can now average over those calculations for comparison with the 2.6r results that are also averaged over x and Q^2 . The first plot shows a comparison of the ALTP data with the old cuts ($W+MM2$ and open circles) and the new ones (W_n+x_{Bj} and filled squares). The dip is shallower. The curves are SJ's from three years ago (solid red curve) which are averaged only over Q^2 and for $x=1$ and WVO's recent ones (dashed red curve) that are averaged over Q^2 and x . The surprising thing is that WVO's calculation has deeper dip since averaging over x tends to make the dip shallower since it is shallower away from $x=1.0$.

2011-10-16 14:59:27

Fig 1. Comparison of ALTP data for 2.6r with old cuts and new and SJ's and WVO's calculation. See text.

Jerry Gilfoyle's Enotebook page 407 - Q^2 -x distribution (gpg)

[Modified Thu Oct 20 17:52:43 2011 (GMT) gpg]

Is there anything I can learn from the distribution of Q^2 -x? This is motivated by the fact that WVOs calculation has kinematically forbidden regions and I want to see where they appear in the data. The line is the picture is drawn from the kinematics of the 'failed' WVO calculations which is well below the lower limits of the data. This may mean that I have to think harder about how I am averaging the WVO calculations.

The other weird thing is the structure in Q^2 at low x. This clearly looks screwy!

2011-10-18 18:04:23

Fig 1. Q^2 -x for 2.6r with Wn cut turned on, fids on.

Click [here](#) to view the object (Root macro) you uploaded.

2011-10-18 20:17:57

Fig 2. Same as Fig 1 with 2D QE cut added.

Click [here](#) to view the object (Root macro) you uploaded.

Look at ALTp with NO cut on x and with/without the 2D QE cuts. This doesn't look so bad!

Fig 3. ALTP for cuts used to make Fig 2.

Click [here](#) to view the object (Root macro) you uploaded.

Turn off the 2D QE cut (right-hand panel)

Click [here](#) to view the object (Root macro) you uploaded.

Now look at the 2.6-GeV, normal torus polarity data. The problem is that without a narrow cut on QE events the dip that we see with the W+MM2 cuts disappears. Maybe we just so results for the 2.6r data? Or we study the evolution of ALTP with x and compare with the WVO and JVO calculations.

Fig 4. Comparison of standard ALTP with more recent QE cuts for 2.6n.

Click [here](#) to view the object (Root macro) you uploaded.

ALTP for 2.6n with the 2D QE cut turned off.

Click [here](#) to view the object (Root macro) you uploaded.

2011-10-19 11:51:40

Fig 5. Q2-x distribution for 2.6n with Wn + 2D QE cut and nothing else on ALTp.

Click [here](#) to view the object (Root macro) you uploaded.

2011-10-20 13:38:20

Fig 6. Q2-x distribution for 2.6n with Wn cut only.

Look at the distribution of xBJ versus p_m. It is now clear why the xBJ cut reduces the statistics. At higher p_m, the Bjorken x distribution becomes very wide so restricting x throws out lots of events.

Fig 7. xBJ-p_m distribution for 2.6n with Wn cut on (no 2D QE cut).

Jerry Gilfoyle's Enotebook page 408 - Tracking results for GMn target (gpg)

[Modified Mon Oct 24 13:30:27 2011 (GMT) gpg]

Below are plots from Socrat showing generated v_z and reconstructed v_z for 6 GeV electrons. The resolution is crappy because the FST seems to be turned off. Toggling the parameters in Socrat.opt has no effect other than to make the reconstruction run longer. Leave this as a mystery to be solved alter.

Fig 1. tracking results from Socrat for GMn target.

Click [here](#) to view the object (Root macro) you uploaded.

End of Notebook.
